Abstract

Two new sponge species, *Haliclona durdong* sp. nov. and *Haliclona djeedara* sp. nov. from the south west of Western Australia are described. Morphologically distinct from each other, both species are assigned to the genus *Haliclona* subgenus *Haliclona*. *Haliclona durdong* sp. nov. individuals are ficiform to lobate, brown to beige in colour and have numerous apical oscules. *Haliclona djeedara* sp. nov. individuals have a massive morphology, green colour, and large funnel-like oscules. The description of these two new species brings the species of *Haliclona* (*Haliclona*) in Australia to 25.

**Key words:** taxonomy, systematics, sponges, Porifera, Haplosclerida, *Haliclona*, new species

Introduction

Chalinid sponges (order Haplosclerida) are global in their distribution, with potentially hundreds of extant species (de Weerdt 2002). While they are found across all depths, they tend to be common in shallower subtidal habitats (de Weerdt 2002). They are one of the most difficult groups to study taxonomically, with highly variable and simple morphological characteristics (de Weerdt 2000, 2002). The Chalinidae are characterised by having an ectosomal skeleton that if present, is a regularly hexagonal, unispicular, tangential reticulation. They have a delicate reticulated choanosomal skeleton of uni-, pauci- or multispecific primary lines regularly connected by unispicular secondary lines (de Weerdt 2002).

Of the four valid genera of chalinid sponges, the genus *Haliclona* consists of sponges of variable morphology and consistency including erect, tube-shaped and branching forms, and both soft and fragile, and firm and elastic consistencies. *Haliclona* was first established by Grant (Grant 1836) for the species *Spongia oculata* Pallas, 1766, reported from England. The genus is speciose with 436 valid species presently recognised worldwide (van Soest et al. 2014) of which 44 have been reported from Australia (Hooper 2012).

*Haliclona* contains six subgenera and the two species described here conform to the largest of these, *Haliclona* (*Haliclona*), on morphological characters. This subgenus is characterised by a very regular, ladder-like reticulation, and an ectosomal skeleton that is unispicular, tangential and isotropic. Spongin can be moderate to abundant (de Weerdt 2002). Currently 23 species of this subgenus are recognised in Australia (Hooper, 2012).

The new species described here were compared with known species from the biogeographic areas surrounding their type localities, principally the temperate Australasian realm (Spalding et al. 2007), but also with species from the Northwest Australian Shelf, Sahul Shelf, Northeast Australian Shelf, Java transitional and Western Indian Ocean ecoregions (Spalding et al. 2007). We examined type descriptions and type material as well as non-type original historical specimens where these had similarities to our specimens. Some of the species names given to Australian specimens by early sponge taxonomists were of European species and may be misidentifications. However, it is important to re-examine these historical specimens to ensure earlier taxonomists had not seen
**durdong sp. nov.** producing salicylilhalamide A across its known distribution while *Haliclona djeedara* sp. nov. does not. Although salicylilhalamide A concentration was found to vary with temperature, it was always present and thus the chemical profile of *Haliclona durdong* sp. nov. makes a useful additional diagnostic character for this species (Thompson *et al.* 1987, Abdo *et al.* 2007).

**Acknowledgments**

We thank the members of the Western Australian Museum Aboriginal Advisory Committee: Irene Stainton, Tony Calgaret, Bev Port-Louis, John Mallard and Carly Lane for encouraging our use of Nyoongar names for the new sponge species.

This work was funded by a University of Western Australian Postgraduate Award to DA, and by the Western Australian Museum. The authors would like to thank curatorial staff in the Australian Museum, Sydney, Natural History Museum, London, Museum National d’Histoire Naturelle, Paris, Museum Victoria, Melbourne and South Australian Museum, Adelaide for the loan of specimens or accepting paratypes. Oliver Gomez (WAM) is thanked for his technical support in processing the samples and capturing light micrographs for this study. Dr. Caine Delacy, David Gull and Linda Abdo are thanked for their assistance with the field collections. Thanks also to Dr. Grace McCormick for her preliminary molecular analyses and helpful discussions. We are grateful to Drs Stephen Whalan, Chris Battershill, Libby Evans-Illidge, and Euan Harvey for their years of interest in working with these species. We thank two referees for their comments on the manuscript.
