Abstract

Two new species of *Stephanotheca* are described from the southeast Gulf of Carpentaria, northern Australia, providing the first tropical records of this genus. *Stephanotheca ipsum* n. sp. is provisionally placed in the genus on the basis of a low ridge of calcification around the edge of the ooecium, which differs from the fully pseudoporous ooecium of *Calyptothea* (Lanceoporidae) and resembles the ‘crowned’ ooecium of *Stephanotheca*, with a central porous area surrounded by a nodular imperforate area. *Stephanotheca ipsum* and *Stephanotheca romajoyae* n. sp. are the only species in the genus with more than one avicularium on some zooids. The latter species is distinguished by high variability in avicularium size, shape, position and orientation; it also shares dimorphic avicularia with *S. ochracea* (Hincks) and is the only species in which they sometimes occur together on the same zooid. This study increases the number of Australian *Stephanotheca* species to four. The Australian species all have smaller primary orifices and variations in ovicell morphology compared with other, all European, species. In *S. ipsum* n. sp. the ooecia are ridged, those of *S. victoriensis* Reverter-Gil et al. have a single row of pseudopores forming an arch, and those of *S. ambita* (Waters) and *S. romajoyae* n. sp. have a relatively large pseudoporous area and smaller, lower nodular imperforate area. None of the Australian species have vicarious avicularia, which are known only from the type species, *S. barrosoi* Reverter-Gil et al.

Key words: Tropical Australia, Indo-West Pacific, *Calyptothea*

Introduction

*Stephanotheca* Reverter-Gil, Souto & Fernández-Pulpeiro, 2012 was erected for nine temperate species previously assigned to *Schizonavella* Canu & Bassler, 1917 (Bitectiporidae), six from the Mediterranean, one from the North Atlantic and two from southern Australia (Victoria and New South Wales). *Stephanotheca* was placed in the Lanceoporidae on the basis of cleithral ovicells, dimorphic orifices, vicarious avicularia (in the type species) and the structure of the ovicell. Within the Lanceoporidae, *Stephanotheca* is closest to *Calyptothea* Harmer, 1957, with which it shares a sinus, adventitious avicularia and vicarious avicularia. *Emballotheca* Levinsen, 1909 lacks a sinus, and *Lanceopora* d’Orbigny, 1851 lacks adventitious avicularia and has erect, stalked and rooted colonies. The most obvious distinguishing character for *Stephanotheca* is the ooecium, which is ‘crowned’, having a circular or semicircular nodular ridge of calcification that resembles a crown, and perforations in a central area only (Reverter-Gil et al. 2012), whereas the ooecium of *Calyptothea, Emballotheca* and *Lanceopora* is evenly perforated.

Only a handful of bryozoan species have been described from tropical Australia west of Torres Strait, which is more than a quarter of Australia’s coastline (Cumming & Tilbrook 2014). Cumming & Tilbrook (2014) described six species of *Calyptothea* from the Gulf of Carpentaria (GoC) Collection held at Museum of Tropical Queensland, Townsville. This study describes two species of *Stephanotheca* from this collection, and is the first record of tropical species of *Stephanotheca*. 
Acknowledgements

I gratefully acknowledge Australian Biological Resources Study for support and the CReefs Australia Project for co-funding to RLC (grant # RF210–11). The CReefs Australia Project was generously sponsored by BHP Billiton in partnership with The Great Barrier Reef Foundation, the Australian Institute of Marine Science and the Alfred P. Sloan Foundation. Kevin Tilbrook generously provided the SEM images. I thank Melissa Beata Martin, Niel Bruce, Paul Muir, Oscar Reverter-Gil and Dennis Gordon for comments that greatly improved the manuscript, and Niel Bruce for mentorship and support.
