Abstract: A faunistic survey on beetles was conducted within the Talassemtane National Park (Western Rif, District of Chefchaouen), in order to improve knowledge of their local diversity, to assess species and provide the first list of heritage species. This is an inventory that took place for 3 consecutive years (2013-2015). Out of 550 species identified so far, 137 are processed in this document, which lists heritage species: 67 endemic to Morocco, 20 rare saproxylic and 48 species new to Morocco, including two new to science.

Key words: Morocco, Talassemtane National Park, heritage value, Coleoptera biodiversity, conservation.

Introduction

The Talassemtane National Park (PNTLS) is one of the six Important Plants Areas (IPA) priorities for conservation actions in the Mediterranean region (Taleb & Fennane 2011). Located in the western part of the calcareous ridge of Rif's mountain range, the PNTLS offers natural landscapes of great heritage value across the Mediterranean. Also, this region hosts the most important of the only two forests of an endemic fir tree *Abies marociana* Trab. and other threatened plant species (Alaoui *et al.* 2011). In addition to its important floristic value, the PNTLS houses a diverse but poorly known wildlife; including insects. Over a quarter of identified animal species are beetles (May 1988) and are the

dominant taxa in forests (Bouget 2004). Therefore it is important for the Forest Department to include the diversity data of Coleoptera while making policy decisions.

Information on beetles and their distribution in Morocco is incomplete in mountainous and forest areas of the Rif, whose exploration is difficult. Studies on PNLTS coleopteran are sporadic and hence do not cover the coleopteran diversity entirely (Escalera 1914; Peyerimhoff 1949; Kocher 1956-1964; Benhalima 2004; Arahou 2008; Mouna 2013). At the PNLTS, invertebrates have been less studied than plants and vertebrates. Few workers have examined flies (Belqat *et al.* 2001), ants (Taheri *et al.* 2014) and water beetles (Benamar *et al.* 2011) of the study area.

In general, no Moroccan or African law, referring to insects' protection exists, and, Morocco does not have a red list of threatened species adapted to its territory such as Europe: only the International Red List of Threatened Species (IUCN) exists as a baseline data. It is, therefore, essential to determine a list of species requiring urgent protection measures.

A survey of beetles of the PNTLS was conducted during 3 consecutive years (2013 to 2015), to establish a first list of heritage species (saproxyllic rare, endemic, new species to the country and to science), which will facilitate the establishment of a management policy to conserve these singular forests of Rif region.

Material and methods

Study area

PNTLS covers an area of 64,601 ha. Two-thirds of the park are within the province of Chefchaouen and one-third belongs to the province of Tetouan. It is mainly formed by the southern portion of the Rifian calcareous ridge and includes the highest summits of the western Rif (e.g. Mounts: Lakraa (2159 m), Tissouka (2122 m), Taloussine (2005 m), Kelti (1926 m) and Tazaout (1791 m)).

The climate of PNTLS is characterized by being the wettest zone of North Africa. The park is characterized by two climax forest stands, formed by an endemic and relict fir species, *Abies marociana* Trab. The Talaassemte fir forest is the largest existing and extends over 2,300 ha. It is located in the province of Chefchaouen, at a distance of approximately 90 km from the Atlantic Ocean and 30 km from the Mediterranean and occupies the high summits of the Park.

The fir tree represents the main essence in this ecosystem, although it shares the territory with other species also important from an ecological point of view, the most important being black pine, maritime pine, cedar, green oak and yew. This floristic richness confers to the site a diversity of high value.

Our survey was carried out in pure fir forests (in the highest zones), as well as in fir-oak (*Quercus ilex*) forests (Fig. 1).

Data collection

Window flight traps, and, in particular, the multidirectional PolytrapTM, were used because they are probably best suited for inventorying saproxylophagous beetles in the temperate forest (Bouget & Brustel 2009). Two other types of traps were used in the inventory: Barber traps to intercept the ground fauna and yellow colored traps to attract the flower-dwelling species (Bouget & Nageleisen 2009).

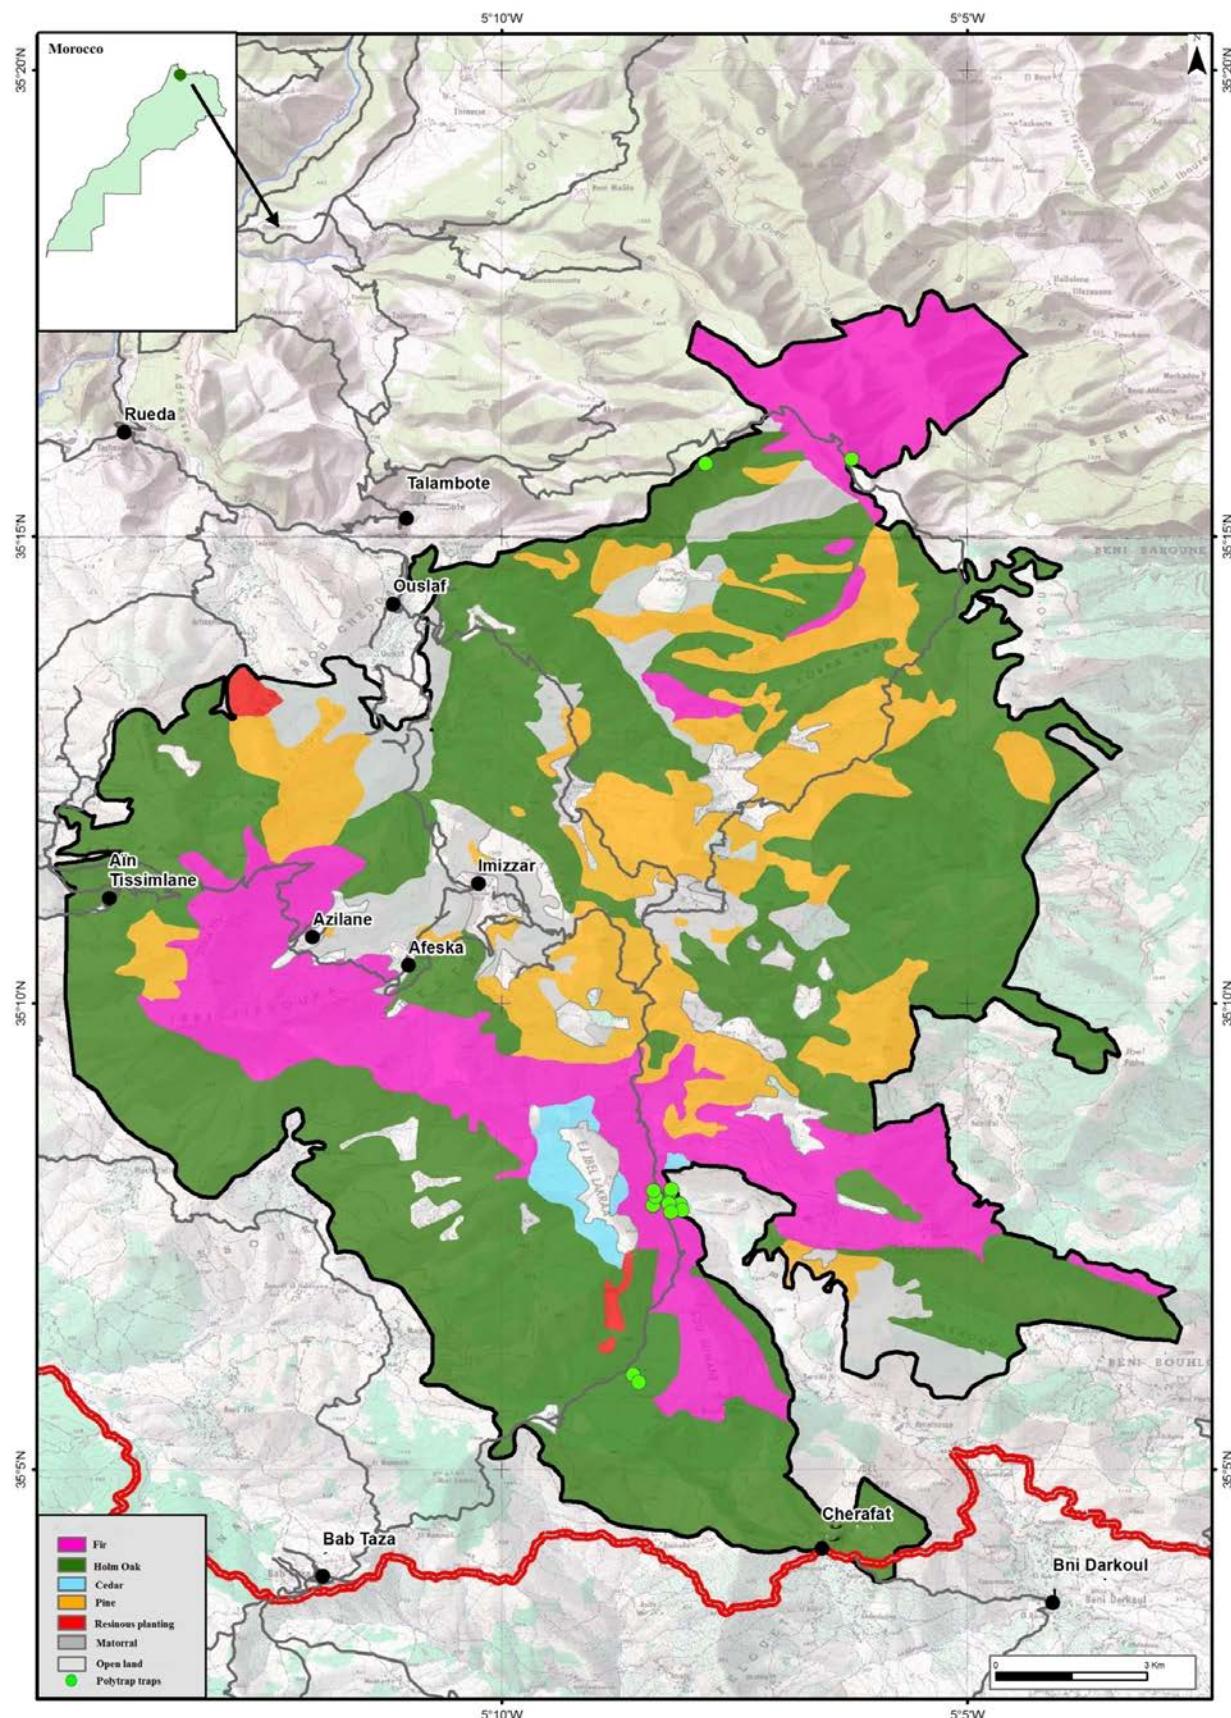

Figure 1. Talassemtane National Park's map showing floristic stands and Polytrap traps localization.

All traps were installed in 20 random plots in the fir grove in 2013 and 2014, and then installed in Oak Grove in 2015. The trap contents were collected once every 15 days, for 7 months (April–October), during 2013 to 2015.

Active collection was done during April 2013, August 2013, October 2013, June 2014, September 2014 and October 2015 most often during the installation of the protocol or the statements of traps. Many active methods were used such as breaking the dead or fallen trees, lifting up the stones and boulders, beating the plants and sifting the litter.

Reference literature and treated species selection

The *Catalogue of Palaearctic Coleoptera* (Löbl & Smetana 2003, 2004, 2006, 2007, 2008, 2011, 2013) and the Commented Catalogue on beetles of Morocco "Catalogue commenté des coléoptères du Maroc" (Kocher 1956, 1958, 1961, 1963, 1964), were referred to designate endemic species and to establish the originality of the new data for Morocco.

Also, we used the *IUCN Red List of Threatened Species* (IUCN), the *European Red List of Saproxylic Beetles* (Nieto & Alexander 2010), the Atlas of threatened invertebrates of Spain (Species critically endangered and endangered species) "Atlas de los Invertebrados Amenazados de España (Especies en Peligro critico y en Pelogro)" (Verdu and Galante 2009), the Red List of Invertebrates of Spain "Libro Rojo de Los Invertebrados de España" (Verdu & Galante 2006), the *Urwald relict species of Germany* (Müller *et al.* 2005), the *Red List of Mediterranean Saproxylic Beetles* which is part of *IUCN Red List of Mediterranean species* (IUCM pers. com.), in order to determine the rare saproxylic species and those threatened.

Results

This sampling has so far identified 550 species belonging to 74 families, of which 191 are saproxylic. Only 137 species considered as heritage species will be treated in this work, according to their status, vulnerability and rarity. Of these, 67 are endemic, 48 species new to Morocco and 20 are rare saproxylic (Table 1).

Discussion

Present study reveals the primary data on the diversity of Coleoptera and adds to the knowledge on Moroccan Coleoptera. Of the 137 species reported in this document, 60 are saproxylic and 22 amongst them are addition to the Moroccan fauna. In fact, saproxylic beetles present a great diversity and a specific ecological requirement, which allow them to be excellent indicators of habitats complexity and forest sites (Brustel 2001). They represent an interesting model for studying forest response to disturbances (Bouget 2004).

In our survey, 20 rare saproxylic species have been recorded in the PNTLS. The rare taxa are a source of interest for conservation because the rarity of a species is defined by its specialization towards habitat (trophic requirements) within its range (Gaston 1994). The presence of rare species in the PNTLS and especially in its fir forests is indicative of a high heritage value but also a need for intervention by managers for their conservation. One species, *Triplax lacordairei* (Crotch, 1870) (Erotylidae) is on the red list in Europe as endangered (EN). A probably new species of *Prostomis* sp. (Prostomidae), which has yet to be described, is likely be close, in its ecology, to a Near Threatened (NT) european species: *Prostomis mandibularis* (Fabricius, 1801). This species was found in red decay of tree trunks lying on the ground. Three other species are on the Red List as at least concern species (LC): *Semanotus laurasii laurasii* (Lucas, 1852) (Cerambycidae), *Ampedus aurilegulus* (Schaufuss, 1863) (Elateridae) and *Temnochila caerulea* (Olivier, 1790) (Trogossitidae). Some species mentioned in this document will eventually be included in the next Red List of Mediterranean saproxylic beetles (IUCM pers. comm.).

Endemic species represent a particular class of rare species (Gaston 1994). 67 species endemic to Morocco are present in the study area and 18 species of them are saproxylic. The Rif Mountains in Morocco and those of the Sierra de Grazalema and Sierra de las Nieves as well as the Sierra Nevada in Spain, all are part of the Baetic-Rif Arc and resulting from the alpine orogeny due to the collision of the African and Eurasian plates. They are part of the Intercontinental Biosphere Reserve of the Mediterranean and are home to two fir species quite similar and threatened, which are *Abies marocana* Trab. and *Abies pinsapo* Boiss. (Vela 2002). This ecological and biogeographical proximity can be illustrated in beetles by the presence of endemic species, as *Eocarterus (Baeticocarus) baeticus* (Rambur, 1837) (Carabidae) which was considered endemic to the Sierra Nevada (Spain) has been found in Morocco for the first time.

Besides the rare and endemic species, 48 were new record for Morocco out of which 4 resulted new to science and were described in recent years: *Otiorhynchus (Lixorrhynchus) incisus* (Curculionidae) (Bialooki *et al.* 2015), *Elathous talassemtani* (Németh *et al.* 2015) (Elateridae), *Globicornis* sp. nov. (submitted by Kadej *et al.* in 2016) (Dermestidae) and

Dienerella sp. (Otero *et al.* submitted). Twenty four species are new to North Africa, among them *Hylis simonae* (Olexa, 1970), cited as Near Threatened (NT) by the red list of IUCN.

This study also allowed the rediscovery of some species, which were known only by the holotype, among them *Kyklioacalles granulicollis* (Tournier, 1875), which was described from Tangier (Morocco) and whose type specimen was missing, hence the neotype was designated by Stüben & Bayer (2015).

The presence of such beetles' biodiversity at the Talassemte National Park can only approve its heritage significance. Managers of this biodiversity hot spot, are required to entrust more interest and conservation efforts, reducing the unsustainable practices (overgrazing, fire...) that exist in this "protected" area. It is essential to make improvements on conservation actions by making more efforts on protecting the last Moroccan fir forests by strengthening forest vigilance and raising awareness of local populations. Sustainable management of this heritage requires taking into account all functions and uses that the PNTLS had to offer (ecological, economic, tourism...) and their integration to management reflections undertaken by the different concerned parties.
