Söderström *et al.* (2013) outlined the current status of the family Lophocoleaceae. Following their concept several new combinations are needed, most of which are made here. While many of the taxa treated below need to be lectotypified, we are generally not doing that here.

We only transfer taxa that have been shown to belong to the new genus in recent studies (molecular and/or morphological) or taxa that have been studied by the authors (see Söderström *et al.* 2013 for further references). There still exist taxa that need to be transferred from *Chiloscyphus*, but we are not transferring them here, since it is unclear to us in which genus they belong.

The format of this note follows Söderström *et al.* (2012) except that we use the Melbourne International Code of Nomenclature for algae, fungi, and plants (ICN; McNeill *et al.* 2012) instead of the Vienna International Code of Botanical Nomenclature (ICBN; McNeill *et al.* 2006).

New combinations in *Cryptolophocolea*

Cryptolophocolea L.Söderstr., Crand.-Stotl., Stotler et Váňa, *Phytotaxa* 97: 39, 2013 (Söderström *et al.* 2013).

Type: *Cryptolophocolea ciliolata* (Nees) L.Söderstr., Crand.-Stotl., Stotler et Váňa, *Phytotaxa* 97: 39, 2013 (Söderström *et al.* 2013)

Note:—It is not fully clear which taxa to include in this genus and which to refer to *Lophocolea* or other genera. In this paper, we include only those taxa that molecular studies have confirmed to belong to *Cryptolophocolea* and taxa that recently have been classified into *Chiloscyphus* subgen. *Connati* (as well as other taxa that are morphologically close to it; cf. Söderström *et al.* 2013). The first group of taxa that follows are transferred based upon molecular evidence provided in Hentschel *et al.* (2007), Glenny *et al.* (2009), Engel *et al.* (2010), Engel & He (2010), Vanderpoorten & Long (2006) and Vanderpoorten *et al.* (2012) in addition to morphology.

≡ *Chiloscyphus pallidus* (Mitt.) J.J.Engel et R.M.Schust., *Nova Hedwigia* 39: 420, 1984 [1985] (Engel & Schuster 1985).

= *Jungermannia multipenna* Hook.f. et Taylor, London J. Bot. 4: 81, 1845, nom. illeg. (ICN Art. 53.1; hom. illeg. non Hook.f. et Taylor 1844: 381) (Hooker & Taylor 1845), syn. fide Mitten (1854: 135). ≡ *Chiloscyphus multipennus* J.J.Engel et R.M.Schust., *Nova Hedwigia* 39: 419, 1984 [1985] (Engel & Schuster 1985).

Note:—When Hooker & Taylor (1844) first described *Jungermannia multipenna*, they inadvertently repeated the diagnosis for *Jungermannia intortifolia* Hooker & Taylor (1844: 374), which is the basionym of *Isotachis intortifolia* (Hook.f. et Taylor) Gottsche (1864: 121; see Hooker & Taylor 1845: 81 where this error was first discussed). This makes *Jungermannia multipenna* 1844 (based on Campbell I. material) a superfluous name (nom. illeg. ICN Art. 52.1) since it was based on the same type as *Jungermannia intortifolia*. Aware of their error, the following year Hooker and Taylor published *Jungermannia multipenna* Hooker & Taylor (1845: 81), based upon Auckland Is. material, but this is also illegitimate as a later homonym (ICN Art. 53.1) since *Jungermannia multipenna* 1844 had already been effectively published. When Gottsche *et al.* (1845) transferred *Jungermannia multipenna* to *Lophocolea* they cited the 1844 publication, technically making this name a synonym to *Isotachis intortifolia*. In Gottsche *et al.* (1847) they tried to correct it with a new combination citing the 1845 basionym, but as the earlier *Lophocolea multipenna* 1845 was effectively published, this later name also became an illegitimate homonym. In 1854 Mitten named *Lophocolea pallida* to include the nom. illeg. "[*Jungermannia*] *Lophocolea multipenna* Hook. fil et Tayl. *Flor Antarct. p.155*" as a synonym, noting that the Auckland Island specimen in Hooker's herbarium is a mix of vegetative shoots of *Leioscyphus decipiens* and a fertile shoot of *Lophocolea pallida*, and that the 1845 description of *Jungermannia multipenna* was compiled from both taxa. When Engel & Schuster (1985) transferred *Jungermannia multipenna* 1845 to *Chiloscyphus*, it could have been considered a valid nom. nov. for all illegitimate names based on *Jungermannia multipenna* 1845 following ICN Art. 58.1 except for the fact that another epithet is available that has priority at that rank, namely *Lophocolea pallida* Mitt. When Engel (1991b) selected a lectotype for *Jungermannia multipenna* 1845 of Hooker plants from Auckland Is., he also reduced *L. pallida* to it, and in fact, all of the illustrations for *Chiloscyphus multipennus* used in his publication were from the type of *Lophocolea pallida*. Based on ICN Art. 58.1, this earlier epithet is the correct name for this taxon and is the basionym for the new combination above.

New combinations in *Lophocolea*

The genus *Lophocolea* was traditionally considered distinct from *Chiloscyphus*, based on morphological characters, until Engel & Schuster (1985) united them. Although their concept has been accepted by some bryologists for about a quarter of a century, for reasons outlined in Söderström *et al.* (2013) a return to a narrower concept of *Chiloscyphus* is now justified. Although most of the combinations into *Chiloscyphus* made by Engel & Schuster (1985) were from *Lophocolea*, the narrower circumscription of *Chiloscyphus* requires that some new transfers from *Chiloscyphus* to *Lophocolea* be made, as detailed below.

Transfer of *Chiloscyphus breutelii* to *Leptoscyphus*

Hentschel *et al.* (2006) showed that *Chiloscyphus breutelii* is nested within *Leptoscyphus*. A position outside *Chiloscyphus* is also confirmed by Glenny *et al.* (2009), but they did not include any *Leptoscyphus* in their study. The oldest name for the taxon is *Lophocolea trapezoïdes*, but it is not available in *Chiloscyphus*.

Transfer of *Chiloscyphus gremmenii* to *Stolonivector*

Chiloscyphus gremmenii was described using a very broad concept of the genus *Chiloscyphus* (*sensu* Engel & Schuster 1985). Molecular analyses of a relatively large number of taxa (e.g., Hentschel *et al.* 2006, 2007) show that within the broadly defined genus were included a number of separate clades, some of which corresponded to described genera (see Söderström *et al.* 2013). Unfortunately, no specimens of the small, morphologically specialized genus *Stolonivector* Engel (1991c: 80) have been included in any molecular study to date. However, we conclude that, with acceptance of a narrower circumscription of *Chiloscyphus* and the additional, better developed material of *Chiloscyphus gremmenii* now available, *Chiloscyphus gremmenii* should be transferred to *Stolonivector* as it agrees with this genus in all characteristics presented by Engel (1991c) except that stolons are not common and gynoecia are on leading shoots. This species is similar to *Stolonivector fiordlandiae* (Hodgson 1953: 340) Engel (1991c: 82) and *Stolonivector obtusilobus* Engel (2009: 337). The differences can be summarized as follows: stolons relatively rare, leaves heteromorphic, of very variable form, sometimes deeply bi-(tri-)lobed, basal part of the leaves bistratose, gemmae present, gynoecia on leading shoots, and perianth mouth entire. Moreover, *Stolonivector gremmenii* has larger cells (25–30 × 20–27 µm) than *Stolonivector fiordlandiae*. Thick-walled cells without trigones and acute leaf lobes separate *Stolonivector gremmenii* from *Stolonivector obtusilobus*.

New synonym in *Chiloscyphus* Corda

In Söderström *et al.* (2013) *Chiloscyphus* is circumscribed to include only taxa that can be assigned to *Chiloscyphus* subg. *Chiloscyphus* as defined morphologically by Schuster & Engel (1985: 409). Relevant characters of the genus include the following: leaves unlobed; underleaves bifid, never connate with the leaves; perianth inflated to slightly prismatic, not sharply keeled; shoot calyptra well-developed, equal in length to the perianth or extending beyond it at maturity; androecia on leading stems, with the male bracts scarcely differentiated from the leaves. As currently defined, we think only four species belong to the genus.
