Abstract

The systematic relationships between *Carduus brutius* and its putatively relative taxa, i.e. *Carduus affinis* and *C. defloratus* subsp. *carlinifolius*, were assessed by means of morphological, morphometric and karyological analyses. Our results highlighted a diploid status ($2n = 2x = 22$) for all the three involved taxa and a higher morphological similarity between *C. brutius* and *C. affinis*, which are also completely allopatric (but collectively sympatric with *C. defloratus* subsp. *carlinifolius*). The names *Carduus affinis* Guss., *C. affinis* var. *brutius* Fiori, *C. affinis* var. *vulturius* Fiori and *C. affinis* f. *pollinensis* Fiori were typified. At the present state of knowledge, a subspecific status seems the most appropriate for *C. brutius*, as *C. affinis* subsp. *brutius*. This taxon can be regarded as schizoendemic, restricted to southern Italy (Montea-Caramolo mountain area, Calabria).

Key words: Apennines, *Carduus affinis*, *Carduus defloratus* s.l., Compositae, endemics, Italy, typification

Introduction

Porta (1879) reported the discovery of a putatively new *Carduus* Linnaeus (1753: 820) species during a field trip carried out in 1877 together with R. Huter and G. Rigo in Monte Mula (Montea-Caramolo mountain area, Calabria, southern Italy). This species was provisionally and informally named “*Carduus brutius*” by that author. Few years later, based on the Huter, Porta & Rigo's collection, *C. affinis* Gussone (1826: 334) var. *brutius* Fiori in Fiori & Béguinot (1904: 356) was described. According to this author, this variety is distinguished by its glabrescent abaxial surface of leaves (vs. white-arachnoid in the typical variety).

Huter (1906), raising this taxon to the species level, completely ignored *C. affinis* and evidenced the affinities of *C. brutius* with *C. defloratus* Linnaeus (1759: 1200) subsp. *carlinifolius* (Lamarck 1785: 700) Ces. in Cattaneo (1844: 302) (the only subspecies occurring in Apennines, see Gremaud 1981d, Conti *et al.* 2005). On the contrary, Lacaita (1918) pointed out again towards an affinity with *C. affinis*, and the same approach was followed by the monographer Kazmi (1964), who recombined the name at the subspecific level and typified it.

Carduus affinis was described from Abruzzo and Molise, central Italy: “In apricis, vel sylvaticis montosis Samnii; Capracotta, Monte Capraro: Aprutii; Majella alla Majelletta, Morrone” (Gussone 1826), and this name is still lacking typification (Peruzzi *et al.* 2015).

According to the recent inventory by Peruzzi *et al.* (2014), *C. affinis* is endemic to central and southern Apennines, from Marche to Calabria, while *C. brutius* occurs only in Calabria, and doubtfully in Basilicata.

As already evidenced in preliminary contributions (Bernardo *et al.* 2013, 2014), *C. brutius* shows intermediate features between *C. affinis* (for the general habit), and *C. defloratus* subsp. *carlinifolius* (for the leaf glabrescence and phyllaries dimensions). Indeed all the three taxa belong to *Carduus* sect. *Carduus* subsect. *Deflorati* Kazmi (1964: 307), albeit placed by Kazmi (1964) in different series (ser. *Candicans* Kazmi 1964: 309 for *C. affinis* and *C. brutius*, ser. *Deflorati* Kazmi 1964: 308 for *C. defloratus* subsp. *carlinifolius*). Moreover, no karyological data (Bedini *et al.* 2012a, 2012b) and cypselae features are available neither for *C. brutius* nor for *C. affinis*, except one count on material
