A revision of the North Atlantic amphipod genus *Normanian* 
(Crustacea: Amphipoda: Lysianassoidea)

Abstract

Members of the lysianassoid genus *Normanian* have previously been difficult to identify, due to uncertainty regarding synonymies and validity among members of the taxon. Here, the genus is reviewed and a full description with illustrations is provided for the four eyed-species. Species are compared and synonymies are resolved.

Key words *Normanian*, Amphipoda, Lysianassoidea, Northeast Atlantic, Mediterranean

Introduction

*Opis quadrirmana*, a species of lysianassoid amphipod, was described from the coast of Banffshire, Scotland, by Bate and Westwood (1868). This species later served as the type for the new genus *Normania* Boeck (1872). However, the latter was homonymous with a genus of Ostracod, and thus, Bonnier (1893) emended the name to *Normanian*.

*Normanian* is a small genus in which there are currently six described species. Species level identification is difficult owing to the superficial similarity of at least three of the species. As a result, these have been placed in the synonymy of each other by various authors at different times. The issue is further confused by the fact that the type of the genus, *N. quadrirmanus*, as described and illustrated by Bate and Westwood, differs considerably from the type material deposited in the Natural History Museum, London (NHML). Bate and Westwood’s illustration shows a denticulate palm on the gnathopod I propodus, and the authors state that “the propodos [sic] of the first pair (of gnathopods) is quadrate, the palm being…armed with a minutely denticulated thickened margin…” However, the type specimen from the NHML, as later redrawn by Lincoln (1979) has a
