### Abstracts

Using published records and original data derived from my research, a checklist was generated of the helminth parasite fauna in 194 native and 18 introduced freshwater fish species from 30 families from Mexico. The checklist contains 262 nominal species, from 152 genera and 59 families of helminth parasites. It includes 37 species of adult trematodes, 52 metacercariae, 49 monogeneans, 15 adult cestodes, 22 metacestodes, 7 adult acanthocephalans, 5 cystacanths, 56 adult nematodes and 19 larval nematodes. Most of these species (150, 57%) are Neotropical, 35 (13%) are Nearctic, and 28 (11%) are either anthropogenically introduced into Mexico (21 of them), or are world-wide in their distribution (7 species). Insufficient data preclude the determination of the status of the rest of the species. Only 18 of these species are tentatively pointed out as endemic to Mexico, although 55 species are recognized as being endemic to Mesoamerica. The data demonstrate that the helminth fauna of freshwater fish in Mexico is divided into Neotropical and Nearctic components with no apparent transition zone between them. The Nearctic fauna mainly consists of allogecic generalist species capable of invading Neotropical hosts and environments, but the Neotropical fauna, mostly autogenic and consisting of specialists to certain host families, is limited to Neotropical environments and hosts. This Neotropical fauna forms part of a Mesoamerican zone that extends from southeast Mexico along the Gulf of Mexico slope and into Central America. Fish families have typical groups of helminth species which allows the spatial distribution of helminths to follow that of

their hosts. Together with their allogenic generalist characteristics, this gives this helminth fauna a broad distribution that covers Mexico's Neotropical and Nearctic basins.

**Key words:** helminths, freshwater fishes, Mexico, biogeography, Trematoda, Monogenea, Cestoda, Acanthocephala, Nematoda

## Introduction

Mexico is one of the five megadiverse countries (together with Colombia, Brazil, Indonesia and Australia) with the highest biological diversity, and where there is a very high number of ecosystem types, large numbers of animal and plant species, and there is a great genetic variation (CONABIO 2005, Mittermeier et al. 1997). Mexico has a diverse freshwater fish fauna. At least 375 freshwater fish species, of which approximately 60% are endemic, occur in Mexico, and if those fish that live in estuaries and coastal lagoons are included there are over 500 species (Miller 1982, 2005, Espinosa-Pérez 1993). High level of endemism, and a very rich mixture of Nearctic and Neotropical elements are characteristic of the Mexican ichthyofauna. Therefore, we might expect there to be a high diversity and endemism of freshwater fish helminth parasites. But no regional, actualized survey of the parasite fauna of Mexican freshwater fish has been published, and reports of helminth parasites are scattered in mostly taxonomic papers throughout the literature.

Research about the helminth parasites of freshwater fish in Mexico has increased dramatically in recent years (see references in present work). Earlier studies were mostly taxonomic work (e. g. Manter 1936, Pearse 1936, Chitwood 1938, Stunkard 1938, Caballero y Caballero & Winter 1954, Lamothe-Argumedo 1970), although surveys of the larger, mostly Neotropical drainage basins in Mexico have been published recently (Salgado-Maldonado et al. 2001a, b, 2004a, b, 2005a, b, c). There have also been analyses of the helminth parasites of some fish families (Salgado-Maldonado et al. 1997, Vidal-Martínez et al. 2001a, Mejía-Madrid et al. 2005, Pineda-López et al. 2005), and the taxonomic data of several helminth groups have been verified (e.g. Scholz 1997, 1999, Moravec 1998, Vidal-Martínez et al. 2001a, Aguirre-Macedo & Scholz 2005, Caspeta-Mandujano 2000, 2005). Despite this growing body of data, records for the helminth parasites of freshwater fish in Mexico remain dispersed, which greatly complicates broader data analysis. In response, the present review is aimed at compiling data on helminth parasite species in Mexican freshwater fish and their current known geographic distribution in Mexico.

Species lists are important because they are needed to successfully document and understand the causes and consequences of biotic diversity. Species lists form a vital element of distribution studies because they aid in generating hypotheses to guide the application of experimental and comparative methods. Another powerful tool in species distribution studies are databases including faunistic status, biological attributes, geographical distribution and species history (Williamson & Filter 1986). Many disciplines in

the biological sciences (e.g. conservation, public health, ecology of invasions, economics, among others) depend on accurate and data-rich public specimen databases. Biodiversity research also requires rich and accessible databases, including specimen-verified taxonomic data that is corrected when necessary (Hoberg 2002, Barger 2004 and references cited therein). Thus, the hope is that this checklist will generally facilitate future research in biodiversity, zoogeography, and ecology, but also directly help conservation, freshwater fisheries and aquaculture researchers.

## Material and methods

Using published records and original data derived from my research a checklist was generated of the reported helminth parasite fauna in native and introduced freshwater fish from Mexico. The species referred to in undergraduate theses and scientific meetings do not constitute formal publications and are consequently not considered herein. Pérez *et al.* (1996) published a list of the helminth parasites of freshwater fish in Mexico that is now outdated. It is not considered in this review because much of the data it contains were taken from unpublished undergraduate theses and abstracts from meetings. Identification veracity was also not done in this list and taxonomic validations available at the time were not included (e.g. review of the *Genarchella* genus by Scholz *et al.* 1995, cited but not considered) meaning this list may contain a number of errors in species denomination.

The checklist is organized as a parasite-host list including host/locality records and arranged phylogenetically by Trematoda, Monogenea, Cestoda, Acanthocephala and Nematoda (Table 1). The phylogenetic classification mainly follows Yamaguti (1971), Gibson (2002), and Jones *et al.* (2005) for Trematoda; Boeger & Kritsky (1993) for Monogenea; Khalil *et al.* (1994) for Cestoda; Amin (1982, 1985, 1987) for Acanthocephala; and the CIH Keys (Anderson *et al.* 1974-1983) and Moravec (1998) for Nematodes. Families, sub-families, and genera are listed in alphabetical order. Data for each species include:

### Scientific name.

Status: Nearctic/Neotropical species location. Allogenic/Autogenic: Allogenics are species that mature in and are transported by birds; Autogenics mature in fishes or other aquatic hosts (see Esch *et al.* 1988). Other indications include if the helminth species are anthropogenically introduced, if they are endemic to a main basin or Mexico, or to Central America (Mesoamerica) overall, or if they have world-wide distribution. A conservative approach is taken in attributing status distribution to species. Species are not presumed to have a limited geographic distribution unless strong evidence to the contrary is available, and thus the list underestimates the number of endemic species rather than overestimates it. Occurrence records of helminth species in Mexican freshwater fishes have been generated during the authors' survey work, though data from exhaustive primary literature review is also included.

Site: Tissue or organ in or on host fish where helminth species has been reported.

Host(s): It is often difficult to decide what is a freshwater fish. I tend to make this work more inclusive, in general including fish species following the criteria of Espinosa-Pérez *et al.* (1993), Castro-Aguirre *et al.* (1999), Miller *et al.* (2005). Host are cited using currently accepted nomenclature as referred by FishBase (Froes & Pauly 2005). A list of fish hosts examined for helminths in Mexico is provided in Table 2.

Record(s): Authors that published records of a specific parasite, by publication date. Data from our own recent research are also included.

Distribution: The distribution records of the helminth parasite species in Mexican freshwater fish are grouped for practical purposes into 9 main hydrological basins (Fig. 1): Río Papaloapan (PAP) (UC abbreviations were used for basins, meanwhile UC and LC abbreviations are for political states, see below); Río Pánuco (PAN); Río Ayuquila in the Sierra de Manantlán Biosphere Reserve (MAN); Río Santiago (SAN); Río Lerma (LER); Río Balsas (BAL); Península de Yucatán (YUC) (data from this region is classified as being from a single basin though the Peninsula lacks surface watercourses, and its sink-holes (cenotes) and other water sources do not constitute a single drainage basin; the Peninsula of Yucatán include 3 states, each locality is also referred to these states, see political division below); Tabasco (TAB), sampling localities from Tabasco comprises the lowlands of the Tonalá, Grijalva and Usumacinta hydrological systems in Southern Mexico; several lakes, shallow, tropical-type were also sampled, some of these lakes have a tidal influence (Santa Anita and El Rosario), which varies with the seasons. Most these lakes have an abundant component of marine and brackish fish species. A though description of these localities can be found in Pineda-López (1994). Data from Chiapas (CHIS) is classified as being from a single basin though records for this region are actually from several reaches of large main drainages, mainly the Grijalva and Usumacinta river systems (Fig. 1). A though description of environments of Mexico can be found in Miller *et al.* (2005). The state of Mexican Republic (Mexico) where each sample locality is situated appears after each locality name. Records from bodies of water that do not belong to any of the above main drainage basins are referred to the state in which they are located. Abbreviations for states are in upper and lower case letters, meanwhile drainages are quoted in upper case (see above). Abbreviations used for the states are the standardized postal abbreviations, i.e. -Baja California, BC; Campeche, Camp; Chiapas, Chis; Coahuila, Coah; Guerrero, Gro; Guanajuato, Gto; Hidalgo, Hgo; Jalisco, Jal; Estado de México, Méx; Michoacán, Mich; Morelos, Mor; Nayarit, Nay; Nuevo León, NL; Oaxaca, Oax; Puebla, Pue; Querétaro, Qro; Quintana Roo, QROO; San Luis Potosí, SLP; Tabasco, Tab; Tamaulipas, Tams; Veracruz, Ver) (see Miller *et al.* 2005). In several cases the Spanish common names for localities do not distinguish between a truly lake (freshwater) or a coastal lagoon (i.e. "Laguna Escondida" at Los Tuxtlas, Ver., it is in fact a freshwater lake), in such cases a precision was made using the appropriate word "Lago" (for any freshwater body) or "Laguna" (for salt or brackish waters of coastal lagoons).

**FIGURE 1.** Mexico, showing main drainage basins from which hosts have been collected and the boundary between the Neotropical and Nearctic biogeographical areas.

Vouchers: Museum and accession (catalog) numbers of the voucher specimens deposited only from the author's collections. Museum names are indicated by the abbreviations: Colección Helmíntologica del Centro de Investigación y Estudios Avanzados del Instituto Politécnico Nacional, Unidad Mérida, Mérida, Yucatán, Mexico (CHCM); Colección Nacional de Helmíntos, Instituto de Biología, Universidad Nacional Autónoma de México, Mexico (CNHE); Colección Parasitológica de la Universidad Autónoma del Estado de Morelos, Cuernavaca, Morelos, Mexico (COPA-UAEAM); Colección Parasitológica de la Universidad Juárez Autónoma de Tabasco, Villahermosa Tabasco, Mexico (CP-UJAT); Helminthological Collection of the Institute of Parasitology, Academy of Sciences of the Czech Republic, Ceské Budějovice (IPCAS); Muséum d'Histoire Naturelle, Genève, Switzerland (MHNG); Natural History Museum, London (BMNH); U. S. National Parasite Collection, Beltsville, Maryland, U.S.A. (USNPC).

A Host-Parasite list is also provided in Table 2.

## Results

The helminth species of parasites of freshwater fishes in Mexico recorded to date are listed in Table 1. Though marine helminth parasites have been recorded in freshwater fish hosts in Mexico they were not included in this list, i.e. the trematodes *Stephanostomum* sp., *Palaeocryptogonymus* sp., *Lecithochyrium floridense* (Manter 1934), *Diptherostomum brusinae* (Stossich 1889), *Helicometrina nimia* Linton 1910, *Torticaecum* sp.; the monogeneans *Encotylabe* sp., *Pseudohaliotrematoides* sp., *Diplectanocotyla* sp., *Neodiplectanum* sp., metacestodes of *Trypanorhyncha* gen. sp., the acanthocephalans *Floridosentis mugilis* Ward 1953, *Dollfusentis chandleri* Golvan 1969, *Gorgorhynchus medius* (Linton 1908), and *Tegorhynchus brevis* Van Cleave 1921; as well the nematodes *Ascaropsis ayalai* and *A. mexicana* Moravec, Salgado-Maldonado & Vivas-Rodríguez 1995, and *Procamallanus (Spirocammallanus) chetumalensis* González-Solís, Moravec and Vidal-Martínez 2002 (see Salgado-Maldonado 1979, Salgado-Maldonado *et al.* 1997, 2005b, López-Jiménez 2001, Vidal-Martínez *et al.* 2001a, González-Solís *et al.* 2002). The recently recorded *Cosmocerca podicipinus* Baker & Vaucher 1984, a nematode parasite of lizards claimed to be recorded in freshwater fish in Mexico (Garrido-Olvera *et al.* 2005) was not included. Also, there were not included in the checklist any helminth species recorded from marine hosts, i. e. *Eugerres plumieri* and species of the genus *Bairdiella*, *Sphoeroides*, *Lutjanus* (see Scholz *et al.* 1994).

Overall recorded data for the helminth parasites of freshwater fish in Mexico show a total of 262 nominal helminth species distributed in 152 genera and 59 families from 3 taxonomic groups: Platyhelminthes (37 adult trematodes, 52 metacercariae, 49 monogeneans, 15 adult cestodes, 22 metacestodes); Acanthocephala (7 adults, 5 cystacanths); and Nematoda (56 adults, 19 larvae). One hundred and fifty of these species (57%) are Neotropical, 35 (13%) are Nearctic, 28 (11%) are either anthropogenically introduced into Mexico (21 of them), or are world-wide in their distribution (the other 7 species). Insufficient knowledge precludes the determination of the status of the rest of the species. Tentatively, only 18 of these species have been indicated as being endemic to Mexico, although 55 species are recognized as being endemic to Mesoamerica (Table 1).

Generalist, mostly allogenic larval helminths, are widely dispersed parasites amongst Mexican freshwater fishes. The metacercariae of *Posthodiplostomum minimum* have been recorded from 10 families and 72 host species; *Centrocestus formosanus* from 12 families, 59 species; *Clinostomum complanatum* from 12 families, 49 species; *Ascocotyle (Ascocotyle) tenuicollis* from 8 families and 40 species, and *Diplostomum (Austrodiplostomum) compactum* from 10 families, 33 species. Also the larvae of several nematodes are widely distributed amongst freshwater fish: *Contracaecum* sp. from 18 families, 67 species; *Spiroxys* sp. from 13 families, 47 species, and *Gnathostoma binucleatum* from 7 families and 22 species.

Several species of adult autogenic helminths are also widely distributed in Mexican freshwater fishes. The trematodes *Crassicutis cichlasomae* has been recorded from 25 spe-

cies of cichlid fish, *Genarchella isabellae* from 18 species of cichlids and *Oligogonotylus manteri* from 12 species of cichlids. The monogenean *Sciadicleithrum bravohollisae* have been recorded from 15 species of cichlids. The acanthocephalan *Neoechinorhynchus golvanii* has been recovered from 7 families and 32 species, 24 of them cichlids. In terms of nematodes, *Procamallanus (Spirocammallanus) rebecca* is known from 4 families and 19 species of mostly of cichlids; *Rhabdochona kidderi* from 7 families, 18 species also mostly of cichlids and *Rhabdochona lichenfelsi* from 16 species of mostly of goodeids. The most widely dispersed adult helminth in Mexican fishes to date is the introduced Asian fish tapeworm *Bothriocephalus acheilognathi* which have been recorded from 7 families and 59 species of freshwater fishes (Table 1).

The Nearctic component is predominantly made up of generalist allogenic helminth species recorded as larvae in freshwater fish (metacercariae, metacestodes, cystacanths, nematode larvae). These biological characteristics contribute to the broad distribution of this fauna among hydrological basins. Part of the Nearctic fauna can also be found in tropical environments in Mexico. In this component, the species *P. minimum*, *P. brevis* and *V. mutabilis* stand out because of their broad geographical distribution and because of they are represented in a large number of host records. The Neotropical fauna mainly consists of autogenic species that are specialists to their host families, do not cross the Neovolcanic Axis and they are not present in the very few Nearctic samples available to date (Table 1).

Two hundred and twelve freshwater fish species distributed in 30 families have been examined for helminth parasites in Mexico (Table 2). The data include 18 species of freshwater fishes introduced to Mexico, i. e. Cichlidae, 10 tilapias plus the convict cichlid, and Cyprinidae, 7 carps. Cichlidae, Poeciliidae and Goodeidae are to date the best studied families of freshwater fishes in Mexico. The data show a rich fauna of helminth species for several cichlids, i. e. *Cichlasoma urophthalmus* with 71 species of helminths, *Vieja synspila* 53 species, *Petenia splendida* 52 species, *Torichthys helleri* 43 species. Fifty species of helminths have been recorded from the heptapterid *Rhamdia guatemalensis*. The characiids *Astyanax fasciatus* and *Astyanax aeneus* have 43 and 23 species of helminths respectively. The eleotrids also have numerous helminth parasites, *Dormitator maculatus* with 32 species and *Gobiomorus dormitor* 29 species. Amongst the poeciliids, *Poecilia mexicana* has the richest parasite record with 28 species. The richest goodeid was *Goodea atripinnis*, with 24 species. Forty helminth species have been recorded from the Asian carp *Cyprinus carpio* in Mexican freswaters, while other cyprinids are like other fish families because they have even less helminths (Table 2).

Most records for helminth parasites in freshwater fishes are from southeast tropical and central Mexico. Most of the sampled localities are in the Neotropics of Mexico, although it should be remembered that a large area of northern Nearctic Mexico has not yet been sampled.

There are relatively high numbers of parasite species from fish in Neotropical southeast Mexico, i. e. Yucatán, Tabasco and Papaloapan, and the west central Sierra de

Manantlán, and comparatively lower helminth species richness in fish in southern and central Mexico, i. e. Balsas and Lerma.

## Discussion

As this study demonstrates, our current knowledge of the diversity of the helminth fauna parasitizing freshwater fish in Mexico is far from complete. Large portions of Mexico remain unexplored for helminths and many of its largest hydrological basins have never been sampled. Most collections to date have been done in Neotropical zones while fish in Nearctic zones have barely been studied. In addition, only a fraction of the freshwater fish families and species in Mexico have received attention, as just 194 of its 375 freshwater fish species have been examined for helminths. Even in the hydrological basins and fish families that have been studied coverage remains incomplete (Salgado-Maldonado 1997, 2001a, b, 2004a, b, 2005b, c, Vidal-Martínez *et al.* 2001a, Mejía-Madrid *et al.* 2005, Pineda-López *et al.* 2005).

The present study is exhaustive and constitutes the most complete list of helminth fauna affecting the freshwater fish of Mexico, including a complete bibliography of research on the subject. Although the data in this fauna list may contain errors derived from different sampling efforts, different geographic coverages or the inclusion of accidental species, it is the only available list for regional comparison of species richness (Holland & Kennedy 1997).

As shown in the present data, the nematode and trematode have the highest species numbers of the helminth parasites of freshwater fish in Mexico (see also Moravec *et al.* 1995f, Salgado-Maldonado & Kennedy 1997, Moravec 2000b). Monogeneans are also a very abundant group and the number of species in it will probably increase with proper sampling for this group (Salgado-Maldonado *et al.* 2005b). There are relatively few cestode species in the freshwater fish of Mexico (Scholz *et al.* 1996), and adult and larval protocephalids constitute the most abundant family in this helminth group (e.g. Pérez *et al.* 1995, García-Prieto *et al.* 1996). In certain hydrological basins, Gryporhynchidae cestodes are also quite abundant (Salgado-Maldonado *et al.* 2001b, Scholz & Salgado-Maldonado 2001). Acanthocephalans are the least abundant taxonomic group of helminth parasites in the freshwater fish of Mexico as was pointed out by Salgado-Maldonado *et al.* (1992).

Neotropical and Nearctic components have been identified within this fauna (see Moravec *et al.* 1995f, 1996, Scholz & Vargas-Vázquez 1998, Aguilar-Aguilar *et al.* 2003b, 2005, Salgado-Maldonado *et al.* 2004a). The Nearctic helminth species component has been assembled from samplings in the Neovolcanic Axis Province (*sensu* Morrone 2005) and nearby regions, particularly the Río Lerma basin and other more northerly waters (Salgado-Maldonado *et al.* 2001b, Aguilar-Aguilar *et al.* 2003b, 2005). The low number of recorded Nearctic species is likely a result of the lack of sampling in the environments, families and species of Mexican Nearctic fish.

The Neotropical helminth component is more numerous. This is largely the result of the broader geographical coverage in Mexico's Neotropical areas and because most of the host families and species examined to date have been Neotropical. A significant portion of freshwater fish species in Mexico are of Neotropical origin, that is, from South America, and many of the Neotropical helminths listed here probably originated with this fish fauna. Fish families such as the characids, cichlids and poeciliids have broadly speciated in Mesoamerica, and this has apparently been an important factor in differentiation among helminth fauna endemic to the region (see Vidal-Martínez *et al.* 2001b).

Twenty one anthropogenically introduced helminth species have been recorded in Mexico to date, and more will likely be recorded with additional monogenean sampling. The presence of introduced species is the direct result of the introduction of Asian carp and African tilapia to Mexico for small scale cultivation, aquarium fish and aquaculture production (Scholz & Salgado-Maldonado 2000, Jiménez-García *et al.* 2001, Salgado-Maldonado & Pineda-López 2003, Pineda-López *et al.* 2005).

Of particular note is that each fish family has a typical helminth fauna and that helminth species distribution corresponds to those of their hosts (Salgado-Maldonado *et al.* 2005b). As a result, both Nearctic and Neotropical helminths are widely distributed among the different hydrological basins of Mexico according to the distribution of their hosts' families. In other words, if a host species is typical of a given environment, its parasites will also be typical of this region. This intimate relationship between hosts and their parasites, and between hosts and their environment, is what determines the regional characteristics of the helminth fauna (Dogiel 1961, Chubb 1963, Wooten 1973, Salgado-Maldonado *et al.* 2005b), such that the composition of a region's parasitological fauna is more influenced by its ichthyological fauna than by limnological factors (Wooten 1973).

A good example of this are the cichlids (Cichlidae), which host a set of typical species including *C. cichlasomae*, *O. manteri*, *Sciadicleithrum* spp., *N. golvani*, *P. (S.) rebecca* and *R. kidderi* (see Salgado-Maldonado *et al.* 1997, Vidal-Martínez *et al.* 2001a). Though some of these helminth species (e.g. *C. ujati*) are distributed only in southeast Mexico, others are distributed with their hosts' family. This is how *C. cichlasomae* is distributed from southeast Mexico to the northern state of Nuevo Leon, while the acanthocephalan *N. golvani* parasitizes cichlids in the southeast as well as on the western and eastern coastal slopes. Cichlids are an abundant component in the fish community of southeast Mexico and therefore the number of helminth species associated with this fish family is predominant in the region's helminthological fauna. In another example, the Goodeinae fauna includes the trematode *M. bravoae* and the nematode *R. lichenfelsi*, which are distributed throughout the Neovolcanic Axis Province and nearby areas, where this subfamily's hosts are found.

The low number of helminth species strictly endemic to Mexico is related to the fact that their distribution follows that of their host families. This means that the distribution of helminth parasites in the Neotropical freshwater fish of Mexico extends to Central Amer-

ica, definitely as far as Nicaragua (Watson 1976, Moravec 1998, Aguirre-Macedo *et al.* 2001a, b, Vidal Martínez *et al.* 2001b, Mendoza Franco *et al.* 2003, González-Solís & Moravec 2004, Scholz *et al.* 2004), and probably to the Isthmus of Panama. This Mesoamerican helminth fauna in freshwater fish differs from that recorded in South America (see Travassos *et al.* 1969, Thatcher 1991, 1993, Ortubay *et al.* 1994, Kohn & Cohen 1998, Kohn & Pinto-Paiva 2000, Moravec 1998, Rego 2000). Vidal-Martínez & Kennedy (2000b) proposed that Neotropical Mexico, and particularly the southeast (the Papaloapan basin, river systems in the state of Tabasco, and the Yucatan Peninsula), form part of a Mesoamerican region. The data here support this proposal because they show that this zone has a distinct helminth fauna and is an area of endemism for the helminths of freshwater fish (see also Aguilar-Aguilar *et al.* 2003b, 2005).

The data demonstrate that the helminth fauna of freshwater fish in Mexico is divided into Neotropical and Nearctic components with no apparent transition zone between them. The Nearctic fauna mainly consists of allogeic generalist species capable of invading Neotropical hosts and environments, but the Neotropical fauna, mostly autogenic and consisting of specialists to certain host families, is limited to Neotropical environments and hosts. This Neotropical fauna forms part of a Mesoamerican zone that extends from southeast Mexico along the Gulf of Mexico slope and into Central America. Because this Mesoamerican zone is one of endemism for the helminth parasites of freshwater fish, its fauna is dissimilar to the Neotropical helminth fauna parasitizing freshwater fish in South America. Fish families have typical groups of helminth species which allows the spatial distribution of helminths to follow that of their hosts. This along with their allogeic generalist characteristics, gives this helminth fauna a broad distribution that covers Mexico's Neotropical and Nearctic basins.

### Acknowledgements

I do appreciate the early advise of Dr. Rafael Lamothe Argumedo and Professor Clive R. Kenndy for the developed of this research. Thanks are due to Tere Novelo Turcotte, Jacob Juárez Arroyo, Leo Aguirre Macedo, Lilia Patricia Ramírez Casillas, Enca Alcolea, Clarita Vivás Rodríguez, Rossana Rodríguez Canul, Joaquín Vargas Vázquez, Sergio Guillén Hernández, Víctor Vidal Martínez, Isabel Jiménez García, Delfina Amaya Huerta, Cris Cañeda Guzmán, Margarito Pérez Rodríguez, Juan José Campos Pérez, Gisela Velázquez Silvestre, Daniel Prado Ancona, Guille Cabañas Carranza, Nancy Minerva López Flores, Alejandra Hernández Rodríguez, Eli Mayén Peña, Rafael Báez Valé, Petrix Sánchez Nava, Juan Manuel Caspeta Madujano, Norman Mercado Silva, Mirza Patricia Ortega Olivares, Ana Lucía Sereno Uribe, Miriam Erandi Reyna Fabián, Guillermo Jiménez Cortés, Griselda Moreno Navarrete, Rogelio Aguilar Aguilar, Andrés Martínez Aquino, Carlos Mendoza Palmero, Guadalupe Lara Figueroa, Jesús Montoya Mendoza, Raúl Pineda

López, Eduardo Soto Galera and Edmundo Díaz Pardo for their assistance with specimens and data collection in the field and laboratory. I do acknowledge field and laboratory work of Frantisek Moravec and Tomas Scholz, who contributed with much new data about helminth parasites of freshwater fishes of Mexico. Thanks are due to Felipe Villegas Márquez for his technical assistance in preparing the illustration. This study was partly funded by SEP- CONACyT project No. P47339455 and CONABIO project no. U005. Special thanks to 2 anonymous reviewers for their suggestions for the improve of the Ms. I appreciate the many valuable helpful suggestions of Dr. Norman Dronen. Same as the Atlas, this work is dedicated to the memory of Obdulio Andrade Salas and Martha Gloria Fucugauchi Suárez del Real former students under Dr. Raúl Pineda López.

| Remarks: Jiménez & Caballero y Caballero (1974) and Guajardo-Martínez (1984) identified this species as <i>Crassicutis bravoeae</i> , whereas Bravo-Hollis & Arroyo (1962) and Pineda-López <i>et al.</i> (1985) identified it as <i>Crassicutis opisthosemensis</i> (see Vidal-Martínez <i>et al.</i> , 2001). Pineda-López <i>et al.</i> (1985) erroneously identified the host <i>Vieja synspila</i> as <i>Vieja fenestrata</i> , and in the same study they used the term "zacatera" for the host <i>Vieja fenestrata</i> (Pineda-López, pers. com.). |                                 |     |   |   |

Remarks: *Phyllodistomum lacustri* is a Nearctic species widely distributed in North America (Canada and USA). Records by Lamothe-Argumedo (1988) and Pérez & Choudhury (2002) apparently corresponds to this species' natural distribution and hosts. All other records doubt this species identification and therefore it must still be confirmed. Several authors have identified specimens either as *Phyllodistomum lacustri* or *Phyllodistomum* sp. (see below). See Vidal-Martínez *et al.* (2001) for a redescription of the species based on specimens collected in cichlids from southern Mexico.

***Phyllodistomum* sp.**

Remarks: Moravec & Salgado-Maldonado (2002) thoroughly discussed the Family position of this genus, previously assigned to Acanthostomidae and to Plagiorchiidae.

**Larval Trematoda**

**Family Acanthostomidae Poche, 1926**

***Atrophecaecum* (?) *astorquii* (Watson, 1976)**

Status: Ne, Au, Em?

Site: Fins, occasionally gills, scales, eyes and swimbladder.

Hosts and records:

Remarks: The "yellow grub" metacercariae has been recorded in Mexican fishes under the names of *Clinostomum intermedialis*, *Clinostomum marginatum*, and *Clinostomum* sp. see Pineda-López *et al.* (1985). We here refer all these records under *Clinostomum complanatum* following Feizullaev & Mirzoeva (1983, 1986) and Gibson (1996).

#### Family Cryptocentridae Ward, 1917

##### *Neochasmus olmecus* Lamothe-Argumedo, Pineda-López & Andrade-Salas, 1989

Status: Ne, Au, Em

Site: Gills

Host and records:

Remarks: metacercariae of "Cryptogonimidae" recorded by Fucugauchi-Suárez del Real *et al.* (1988), Pineda-López (1994), and Pineda-López *et al.* (1985) belongs in *Tabascotrema verai* (see Vidal-Martínez *et al.* 2001). These metacercariae are abundant in cichlid fishes; less frequent cryptogonimid metacercariae in cichlid fishes belongs to *Olmecla laurae*.

**Cryptogonimidae gen. sp./ CNHE 4837, 5308, 5309, USNPC 94419**

Status: Ne?, Au

Site: Eye (humor body), fins, gills, muscle of fins, intestinal wall, gall bladder

Remarks: This species had been recorded as "Neascus" and as *Posthodiplostomum minimum* by Pineda-López *et al.* (1985); as *Posthodiplostomum* sp. by Pineda-López (1985b), Aguirre-Macedo & García-Magaña (1994), Salgado-Maldonado *et al.* (1997) and by Salgado-Maldonado & Kennedy (1997). Very few boucher specimens have been preserved, such that it has not been possible the identification of these metacercariae. These records are listed here under *Posthodiplostomum minimum* following Vidal-Martínez *et al.* (2001). See descriptions of specimens by Pineda-López (1985), Aguirre-Macedo & García-Magaña (1994) and Vidal-Martínez *et al.* (2001).

***Posthodiplostomum* sp.**

Status: Na?, Al

Site: Muscles, gills, body cavity, mesentery, eyes, liver, brain, kidney

Remarks: These metacercariae had been identified as *Posthodiplostomum* sp. by Scholz *et al.* (1995c) and Salgado-Maldonado *et al.* (1997) see Vidal-Martínez *et al.* (2001). Some of the records could be related to *Posthodiplostomum minimum* metacercariae; however, absence of deposited vouchers makes impossible to decide which species were in fact studied.

Remarks: Diplostomid metacercariae have been reported from different surveys. Pineda-López *et al.* (1985a) suggested the metacercariae from muscles of *Ictalurus furcatus* they collected from Chiapas, could be *Hystericomorpha triloba*. Pineda-López (1994) recorded metacercariae as *Diplostomum* sp. 1, 2 and 3. Specimens identified as Diplostomidae gen. sp. were recorded by Vidal-Martínez *et al.* (2001) from several species of cichlids from Tabasco and the Yucatán Peninsula.

Remarks: Pineda-López (1994), Salgado-Maldonado & Kennedy (1997) and Salgado-Maldonado *et al.* (1997) reported metacercariae of *Ascocotyle (Ascocotyle) leighi* from the heart, gills, branchial chamber, kidney, and mesenteries of several species of cichlid fish mostly from southern Mexico. These specimens were identified erroneously. Here all these are included under *Ascocotyle (Ascocotyle) tenuicollis* following Scholz *et al.* (2001a).

***Ascocotyle (Leighia) chandleri* Lumsden, 1963**

Status: Na, Al

Site: Intestinal wall

Remarks: Quoting Moravec (2001b), Sudarikov (1960) analysed the description of Mexican specimens by Caballero y Caballero (1948) and concluded that, in fact, it was *Herpetodiplostomum caimanicola* (Dollfus, 1935). Moravec (2001b) cast doubts about this determination suggesting it may well be *Pseudoneodiplostomum groschafii* Moravec, 2001 an species described by him from Yucatanese and Cuban crocodiles. Scholz *et al.* (1995c) reported this metacercariae as Proterodiplostomidae gen. sp. 1.

#### Proterodiplostomidae gen. sp. 2 of Scholz *et al.* 1995

Status: ?, Au

Site: Swimbladder and gills, muscles, rarely liver, gonads and gills

| Remarks: Identified as "Ancyrocephalidae" in Pérez <i>et al.</i> (2000). Mendoza-Franco <i>et al.</i> (1999) reported on this species as <i>Urocleidoides anops</i> Kritsky & Thatcher, 1974, however, see Mendoza-Franco <i>et al.</i> (2003). A preliminary morphological differentiation suggest 4 "morphotypes", one in each of the fish families: Cichlidae, Centrarchidae, Characidae and Poeciliidae. |                                    |     |  |  |

| Remarks: The type host of this species was referred as <i>Thorichthys aureus</i> (= <i>Cichlasoma aureus</i> ) by Salgado-Maldonado (1978), however, the only cichlid species inhabiting Lago Catemaco is <i>Vieja fenestrata</i> see Miller & Smith (1998), therefore, I refer here type host as <i>Vieja fenestrata</i> . Morphological analysis suggest two cryptic species are mixed amongst present records, the original <i>Neoechinorhynchus golvari</i> associated to cichlid hosts, plus a second Neoechinorhynchid worm parasitizing Eleotrid hosts. |                                     |     |  |   |

Remarks: Following Moravec (1998), Moravec & Huffman (1988, 2001), and Moravec *et al.* (1995f, 1999b), 2 subspecies can be distinguished: the endemic to Yucatán region *Rhabdochona kidderi kidderi* Pearse, 1936 mainly in *Rhamdia guatemalensis*, also in *Ogilbia pearsei*, juveniles in *Gambusia yucatana*. The second subspecies, *Rhabdochona kidderi texensis* Moravec & Huffman, 1988 parasitizes principally fishes of the family Cichlidae *Cichlasoma* spp. (juvenile forms also from mosquito fish *Gambusia affinis* from Texas, USA). *Rhabdochona kidderi kidderi* was also reported from *Parachromis friedrichsthalii*, *Herichthys pearsei*, *Vieja intermedia*, and *Tilapia* sp. from southern Mexico by Vidal-Martínez *et al.* (2001) but no precise relationship host - locality was given in this work. \*Since only juvenile worms were collected from *Gambusia yucatana* by Moravec *et al.* (1995f) these authors pointed out this is a paratenic hosts.

***Rhabdochona lichtenfelsi* Sánchez-Álvarez, García-Prieto & Pérez, 1998** CNHE 4825, COPA UAEM N - 54

Status: Ne, Au, En

Site: Intestine

Remarks: following Moravec (1998) and Moravec *et al.* (1995g), it is possible to separate between 2 "forms", *Contraecum* type 1 and type 2; we here refer both forms together because several other authors did not distinguish the same way. According to Moravec *et al.* (1995g) adults of type 2 larvae may belong to the group of species of *Contraecum microcephalum* (Rudolphi, 1819), *C. multipapillatum* (von Drasche, 1882), *C. micropapillatus*, *C. caballeroi* (Bravo-Hollis, 1939), *C. plagiaticum* (Lent & Freitas, 1948, among others, parasitizing mainly fisheating birds.
