Abstract

Anopheles (Nyssorhynchus) oswaldoi (Peryassú, 1922) comprises a species complex in South America. To fully characterize other taxa within the Oswaldoi Complex, it is essential to fix the identity of the nominotypical member. Given that the no type was designated in the original description, a lectotype is formally designated from the remaining syntypes in the Museu Nacional do Rio de Janeiro. These and other recently collected specimens from the type locality (Espírito Santo, Brazil) and the State of São Paulo, Brazil were used to redescribe the species using morphological characters of the adult female, male and male genitalia, and the fourth-instar larva and pupa. The larva, pupa, and male genitalia are illustrated. Diagnostic morphological characters of the adult female and male genitalia are provided to distinguish An. oswaldoi s.s. from the morphologically similar An. konderi, An. galvaoi, and An. ininii. DNA sequence data from the second nuclear internal transcribed spacer region (ITS2) are included to fix the molecular identity of An. oswaldoi s.s.

Key words: Anopheles oswaldoi; lectotype; redescription; Nyssorhynchus, ITS2

Introduction

Anopheles (Nyssorhynchus) oswaldoi (Peryassú, 1922) was first described as a species of the genus Cellia, based on adults collected in Vale do Rio Doce, Espírito Santo and Baixada Fluminense, Rio de Janeiro, Brazil. At more or less the same time that Dyar (1923) synonymized An. oswaldoi with An. tarsimaculatus Goeldi, Bonne (1923, 1924) recognized two “races” of An. tarsimaculatus, one exophilic and characterized by a small dark basal ring on the hindtarsal segment 2 (= An. oswaldoi) and An. aquasalis Curry, which was reported in coastal areas. Root (1924) examined the male genitalia of An. oswaldoi and An. tarsimaculatus and, considering them identical, once again synonymized the two species. Later, An. oswaldoi was resurrected from synonymy with An. tarsimaculatus based on morphological differences in the adults, larvae and pupae of both species (Lima 1928). Anopheles aquaceaelestitis Curry was first described as a variety of An. tarsimaculatus and later synonymized with An. oswaldoi (Senevet & Abonnenc 1938). Galvão & Lane (1937) suggested that An. oswaldoi consisted of three subspecies, An. oswaldoi oswaldoi, An. oswaldoi var. metcalfi Galvão & Lane and An. oswaldoi var. noroestensis Galvão & Lane. In 1942, Galvão & Damasceno described An. konderi from specimens collected in Coari, State of Amazonas, Brazil, and considered An. noroestensis to be a distinct
