Abstract

Neolucanus baongocae new species is described from Lam Dong Province (Central Vietnam) and compared to closely related *Neolucanus* taxa.

Key words: Taxonomy, Coleoptera, Lucanidae, *Neolucanus baongocae*, new species, *Neolucanus fuscus*, description, Vietnam

The genus *Neolucanus* Thomson, 1862 (Coleoptera: Lucanidae: Lucaninae), is distributed in the Oriental region and islands of Japan. Krajcik (2003) included 58 species within the genus. Fifteen additional species have been described since 2004:

Neolucanus svenjae Schenk, 2004
Neolucanus Chiangmaiensis Schenk, 2006
Neolucanus fiedleri Schenk, 2006
Neolucanus shaanxiensis Schenk, 2008
Neolucanus inaharai Okuda, 2009
Neolucanus benoiti Schenk, 2009
Neolucanus quangxii Schenk, 2009
Neolucanus suzumurai Fujita, 2010
Neolucanus pseudovicinus Fujita, 2010
Neolucanus hagiangensis Fujita, 2010
Neolucanus ijimai Fujita, 2010
Neolucanus guizhoui Schenk, 2011
Neolucanus chongguo Schenk, 2012
Neolucanus punctulatus Quangthai & Schenk, 2013
Neolucanus latissimus Schenk, 2013

Specimens of *Neolucanus* collected in May 2013 at Bidoup—Nui Ba National Park (Lam Dong Province, central Vietnam) were identified as a new species. A comparison of the habitus shows that the new species, *Neolucanus baongocae* **new species**, is different from all other species of *Neolucanus*. Each male mandible has a long, large carina protruded upward and inward along the upper side, which is not present in other species.

Collections examined:

BNHM: Natural History Museum, London, United Kingdom

CMNO: Canadian Museum of Nature, Ottawa, Canada.

LBC: Dr. Luca Bartolozzi's private collection, Italy

LXC: Le Xung's private collection, Hanoi, Vietnam

Dao, is instead *N. similis*. **The *Neolucanus maximus* group**, which has stout mandibles, a robust body and a broad canthus. Some species have two vertical teeth on upper side of each mandible. This group includes: *N. angulatus*, *N. baladeva*, *N. giganteus*, *N. insulicola*, *N. maedai*, *N. maximus*, *N. okinawanus*, *N. perarmatus*, *N. protogenetivus*, *N. saundersi*, and *N. tanakai*. (Fujita [2010] downgraded *N. spicatus* to a subspecies of *N. giganteus*). Tsukawaki (2011) described a new species *Neolucanus katsuraorum*, very close to *N. maedai*; very few characters differ between the two, and *N. katsuraorum* may be a synonym or subspecies of *N. maedai*.

I did not assign the species below to any above groups because of a lack of literature in my library: *Neolucanus lividus*, *Neolucanus maculosus*, and *Neolucanus palmatus*.

The female of *Neolucanus baongocae* can be easily distinguished from females of *N. lividus*, *N. palmatus*, and *N. maculosus* by the following characteristics: female of *N. baongocae* reddish black on disc and black at margins of pronotum, whereas body of female of *N. lividus* entirely black; pronotum of female of *N. palmatus* and *N. maculosus* entirely brownish black (Mizunuma & Nagai, 1994).

The new species, *Neolucanus baongocae*, possesses a long upward and inward carina on each mandible. It does not exhibit the characteristics of any of the above groups.

In comparing habitus with other species, the new species, *Neolucanus baongocae*, is closest to the medium form of *Neolucanus fuscus* Didier, 1926, from Tam Dao National Park (Vinh Phuc, Vietnam). *Neolucanus baongocae* can be distinguished from *N. fuscus* by the following combination of characters:

mandibles of large males of *Neolucanus baongocae* proportionally shorter than those of large males of *N. fuscus*; *N. baongocae* with an upraised carina inside the bend of male mandible

pronotum surface red with black margins (totally black in *N. fuscus*)

submentum strongly concave (flat in *N. fuscus*)

Lateral margin of pronotum slightly concave between anterior angle and lateral one (straight in *N. fuscus*)

Note on the natural history and habitat. The new species, *N. baongocae*, was found in an undisturbed forested mountain area of Bidoup—Nui Ba National Park, Lam Dong Province. Specimens were collected during the day and when walking around and at night by light traps. The elevation of the collection site was 1550–1623m. The new species was collected on dense, foggy days. The forests at collecting points are characterised by medium-sized trees and high humidity.

Acknowledgements

This research was supported by the National Foundation for Science and Technology Development (NAFOSTED) with grant number 106.15-2011.62.

I thank the following colleagues: Do Manh Cuong and Le Xung (Hanoi, Vietnam), who helped in collecting part of the material used in this study; Le Van Huong, Director of Bidoup—Nui Ba National Park, and Nguyen Van Ty, Ngo Van Huyen, Nguyen Van Thuc, and Nguyen Van Minh, who helped at the study site. Klaus-Dirk Schenk (Germany) provided useful comments; Paul Schoolmeesters (Belgium) provided useful literature; and Paul Moler (United States of America) revised the English text.
