### Abstract

Two new species of the parasitic wasp genus *Mesocentrus* Szépligeti (Betylobraconinae) are described. One based on a new species from Papua New Guinea, the other the first Palaearctic member of the subfamily based on a 30+ mya, species from Baltic amber. The second species is illustrated using synchrotron X-ray microtomography. Whereas the extant Betylobraconinae are restricted to Australia, New Guinea and New Caledonia, their ancestral distribution is now known to have extended considerably further. A key to the four species of *Mesocentrus* known from Papua New Guinea is provided. Both species possess some putatively plesiomorphic characters absent in other extant *Mesocentrus* spp. The new extant species differs in having a considerably larger number of antennal segments and a less laterally depressed frons, while the extinct one has the clypeus separated from the face dorsally and strongly developed hypoclypeal depression. Availability of sequence data for this species enabled further analysis of the relationships of the subfamily, which we present in a phylogenetic analysis additionally including the release of a number of new sequences of related taxa.

**Key words:** *Betylobracon*, *Rhinoprotoma*, distribution, fossil, palaeontology, historical biogeography, new taxa

### Introduction

Since its description by Tobias (1979), the Betylobraconinae has undergone expansion and subsequent contraction. It was based on a highly derived Australian genus, *Betylobracon*, which despite not being physically cyclostome, displayed other characters such as possession of hind wing vein m-cu, suggesting that it probably belonged to that group. Van Achterberg (1984) recognised that it was related to the less derived and distinctly cyclostome genus *Mesocentrus* described from Australia by Szépligeti (1900), both genera possessing robust legs with the fore tarsal segments shortened and telotarsus enlarged. Subsequently, three further tribes were added to the subfamily; van Achterberg added the Facitorini for three new tropical genera, and the Planitorini for the Australian genus *Planitorus*, and Belokobylskij & Long (2005) added the Aulosaphobraconini for their new genus *Aulosaphobracon* from Vietnam. However, Belokobylskij *et al.* (2008) using DNA sequence data showed that the Facitorini were actually not close to *Betylobracon* and *Mesocentrus*, but instead belonged in the rogadine tribe Yeliconini, and further, they showed that most probably *Aulosaphobracon* belonged elsewhere, although in the absence of strong support for any other placement they left it the Betylobraconinae. Sharanowski *et al.* (2011) then showed that *Planitorus*, which like *Betylobracon* is not physically cyclostome, was really not a member of the cyclostome braconid lineage at all, but rather a member of the non-cyclostome subfamily Euphorinae. Thus the Betylobraconinae now comprises just *Betylobracon* and *Mesocentrus*, with *Aulosaphobracon incertae sedis* but most likely belonging to the Lysiterminiae.

The extant specimen described here was collected as part of the *Our Planet Reviewed—IBISCA Niugini 2012–2013* project, which operated Malaise traps along an altitudinal transect at Mt. Wilhelm in Madang Province, New Guinea. By coincidence, two of us (DLJQ and TVDK) were studying a cyclostome wasp specimen from Baltic amber in the collection of Copenhagen University museum also apparently belonging to *Mesocentrus*, and we are therefore describing the two species together, and so extending the known range of the subfamily into the palaeo Palaearctic.

Despite being collected quite commonly, nothing is known about the biology of Betylobraconinae. They appear closely related to the cyclostome subfamily Rogadinae, and may belong there, but they are kept separate here as they appear to be distinguishable on the basis of wing venation and metasomal tergal sculpture features. The new taxon was successfully sequenced both for the barcoding region of cytochrome oxidase 1 and for the D2-D3 region of the nuclear 28S ribosomal DNA gene, making it only the second betylobraconine to be known from both gene fragments. We therefore carried out a molecular phylogenetic analysis including a range of related taxa in order better to assess the affinities of the subfamily.

## Material and methods

**Descriptive taxonomy.** The type specimen of the extant species is deposited in the Muséum national d'Histoire naturelle, Paris, and that of the extinct species in the Natural History Museum of Denmark, København.

Wing vein terminology follows Sharkey & Wharton (1997); other terminology follows van Achterberg (1988). The † is used to indicate fossil taxa. Illustrations were made using an Olympus SXZ16 microscope with automated multiple image capture at preset focal levels using an Olympus DP72 camera, and image combination using the Cell^D image processing system.

**Molecular analysis.** Molecular methods were as in Zaldivar-Riverón *et al.* (2008b, 2013). Sequence data for the two gene fragments were assembled from a range of putatively related taxa (see Appendix 1 for Genbank accessions numbers and additional voucher information). The taxa chosen focused on the cyclostome branch including these groups and was rooted by *Doryctes erythromelas*, a relatively basal doryctine (Zaldivar-Riverón *et al.* 2008). Secondary structure interpretation followed the model of Gillespie *et al.* (2005), though with this more taxonomically restricted subset of taxa it was possible to identify a few additional pairing bases than in other recent studies on larger groupings (e.g. Zaldivar-Riverón *et al.* 2008a,b; 2013).

Data were analysed using the maximum parsimony programme RAxML (Stamatakis, 2006) with five data partitions, the three codon positions for CO1 and pairing and non-pairing bases for 28S; length-variable unalignable regions were excluded. The final analyses were carried out over the RAxML were carried out via the webserver interface (Stamatakis *et al.* 2008) which included 100 full bootstrap pseudoreplicates (file execution time approximately 30 minutes).

**Synchrotron X-ray microtomography.** Tomographic scans were performed at the TOPO-TOMO beamline of the ANKA Synchrotron Radiation Facility of Karlsruhe Institute of Technology. 2,500 radiographic projections covering an angular range of 180° were acquired using a filtered white beam with the spectral peak at about 15 keV. An indirect detector system composed of a 50 µm LuAG Ce scintillating screen, diffraction limited optical smicroscope and 12 bit pco.dimax high speed camera (2016 x 2016 pixels resolution) was employed to capture the projections. A 5x optical magnification led to an effective pixel size of 2.44 µm. The frame rate was set to 150 images per second, resulting in an overall scan duration of 16.6 seconds.

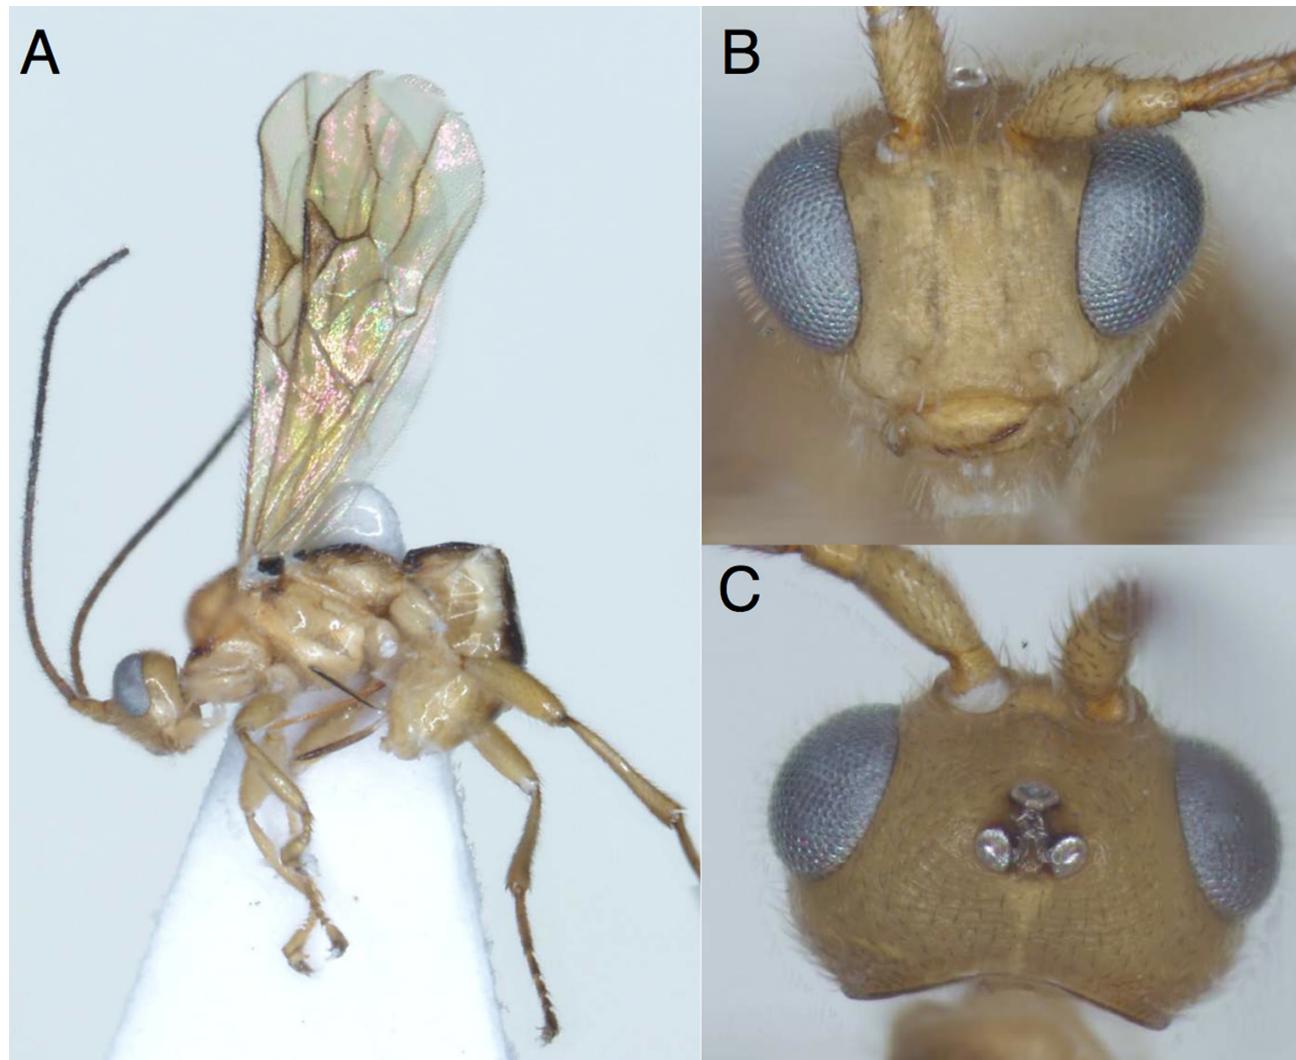

Before reconstruction, the projections were processed with the phase retrieval ImageJ plugin ANKAphase (Weitkamp *et al.* 2011). Volume reconstruction was done by the PyHST software developed at the European Synchrotron Radiation Facility in Grenoble, France.

**Visualisation.** The tomographic volume was imported into Amira® (version 5.5.0; FEI Visualization Sciences Group). The specimen was selected from the tomographic volume by its greyscale using the *Threshold* tool. Artifacts, bubbles and inclusions of dirt were removed manually with *Brush* and *Lasso*. Subsequently, a polygon mesh was created with the *SurfaceGen* module. The polygon count of the original mesh was reduced to 10% of its original value. The mesh was saved in the Wavefront format (OBJ) and imported into CINEMA 4D (version 14; Maxon Computer GmbH) to create the renderings (Figs 4–7).

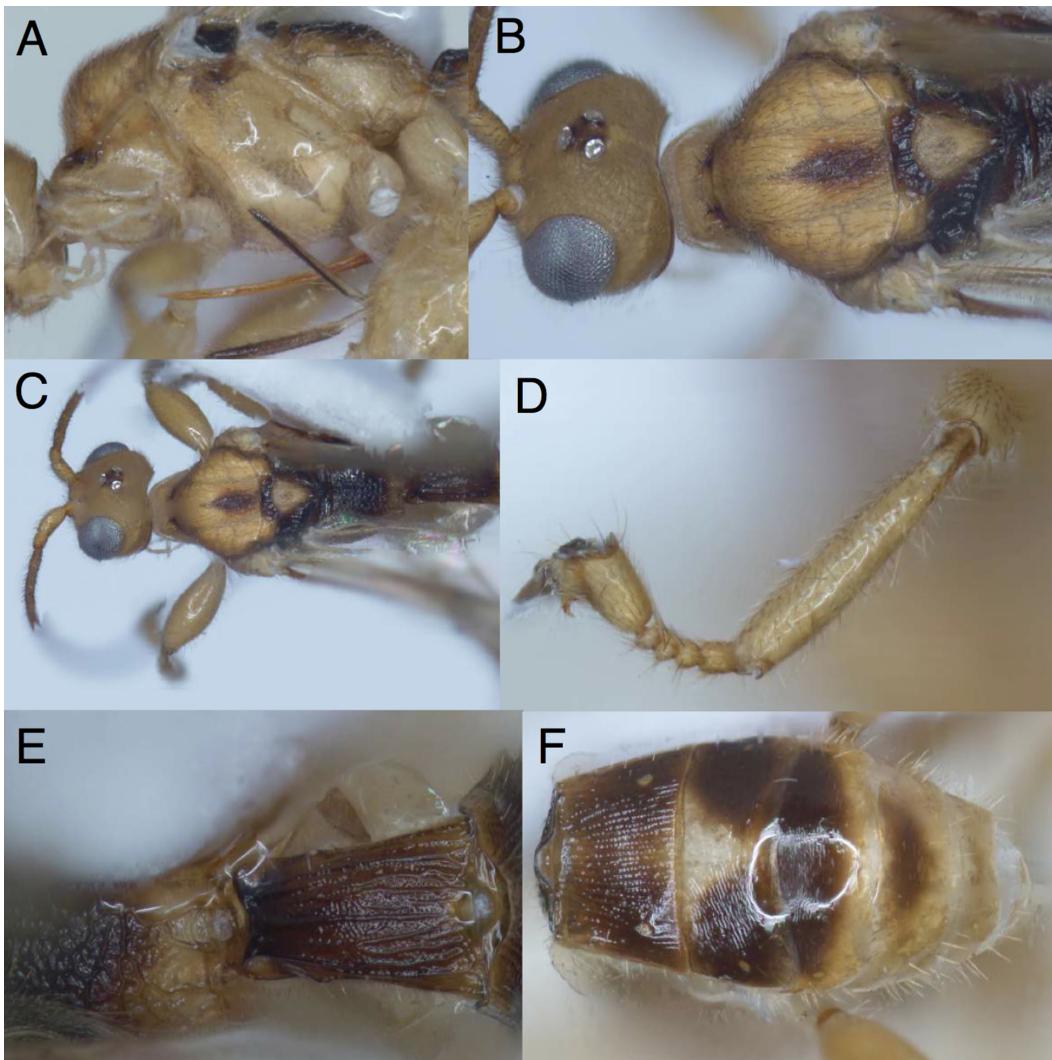

## Key to the species of *Mesocentrus* from Papua New Guinea

The following key is largely based on original descriptions (Szépligeti 1900, 1902) together with Papp (2005). The female lectotype and one male paralectotype of *M. crassipes* and the type and only known specimen of *M. pusillus* have been lost, so it is therefore impossible to be completely sure about all the features of *M. pusillus* and at some point, a neotype is likely to be needed.

1. Antenna with more than 25 flagellomeres (26) (Fig. 1A); frons hardly depressed behind antennal sockets and laterally (Fig. 1C)..... *M. sasquatch* sp. nov.
- Antenna with fewer than 16 flagellomeres (13–15); frons more strongly depressed laterally ..... 2
2. 3<sup>rd</sup> metasomal tergite distinctly longitudinally striate basally; 2<sup>nd</sup> metasomal tergite approximately as long as posteriorly wide (“fast quadratisch”); pterostigma entirely light brown ..... *M. pusillus* Szépligeti
- 3<sup>rd</sup> metasomal tergite entirely smooth basally; 2<sup>nd</sup> metasomal tergite 1.35 to 1.8 x wider posteriorly than long; pterostigma either yellow brown with a darker median spot (*M. crassipes*) or brown with distinct yellow base (*M. reptus*) ..... 3
3. Flagellum not narrowing (attenuating) distally, 1st flagellomere approximately 2 x longer than wide; head rather strongly narrowing immediately behind eyes; pterostigma yellow brown with a darker median spot; 2<sup>nd</sup> ..... *M. crassipes* Szépligeti
- Flagellum strongly narrowing (attenuating) distally, 1st flagellomere approximately 4 x longer than wide; head nearly parallel-sided immediately behind eyes; pterostigma brown with distinct yellow base ..... *M. reptus* Papp

**FIGURE 1.** *Mesocentrus sasquatch* sp. nov. A, habitus; B, head, front view; C, head dorsal view.

**FIGURE 2.** *Mesocentrus sasquatch* sp. nov. A, mesosoma and ovipositor, lateral view; B, thorax, dorsal view; C, head, mesosoma, fore femora, dorsal view; D, fore tibia and tarsus; E, propodeum and 1<sup>st</sup> metasomal tergite, dorsal view; F, metasomal tergites 2–6, dorsal view.

### Descriptive taxonomy

#### *Mesocentrus sasquatch* sp. nov.

(Figs 1–3)

Holotype ♀. Papua-New-Guinea, Province Madang, Mount Wilhelm 1700m (-5.759269,145.2356) 1700m, 09-10/11/2012, leg Valeba, Tulei, Novotny, Leponce, Plot 1, understorey; Malaise—MAL-MW1700A-16/16-d16.

Body length (corrected for bent metasoma) 3.5 mm, length of fore wing 3.0 mm.

Antenna with 26 flagellomeres. Terminal flagellomere pointed but not acuminate. Face transversely striate. Clypeus not separated from face medially. Eyes strongly setose, 1.1 x higher than width of face. Hypoclypeal depression moderately convex mediadorsally, rather shallow with labrum wide and largely exposed. Inter-tentorial distance 2.3 x shortest distance between tentorial pit and eye. Frons hardly depressed laterally. Mesosoma 1.6 x longer than maximally high. Pronotum without midlongitudinal carina. Mesopleuron smooth and shiny. Precoxal sulcus rugose to rugulose, approximately triangular in shape. Median area of metanotum with complete midlongitudinal carina. Fore wing vein 3RSa 3.6 x r-rs, 0.55 x 3RSb. Vein (RS+M)a weakly sinuous. Hind wing vein 1M 1.2 x M+CU. Vein m-cu weakly antefurcal. Hind basitarsus approximately 9 x longer than deep, approximately the same length as the next three segments combined. Propodeum largely irregularly rugose. First

metasomal tergite 1.4 x longer than posteriorly wide with prominent midlongitudinal carina (Fig. 2E); second metasomal suture narrow, shallow, sharply defined, nearly smooth. Metasomal tergites 3 to 5 progressively less conspicuously with fine, sub-transverse wrinkles, with sparse long setosity posteriorly. Ovipositor sheath 0.6 x hind tibia. Ovipositor distinctly laterally compressed.

Largely brown-yellow; dark brown are medioposterior mesoscutum, scutellar sulcus, sides of scutellum and axilla, anteromedial part of propodeum, 1<sup>st</sup>, and tergites, 3<sup>rd</sup> tergite except medio-anteriorly, 4<sup>th</sup> and 5<sup>th</sup> tergites broadly medially.

**Etymology.** Named after the cryptozoological North American creature, big-foot, otherwise known as the sasquatch; noun in apposition.

**FIGURE 3.** *Mesocentrus sasquatch* sp. nov. wings.

***Mesocentrus palaeoeuropaea* sp. nov. †**  
(Figs 4–7)

Holotype ♂. Braconidae/C.V. Henningsen [the collector]/22-6-1953 [the collecting date]. No further information is available.

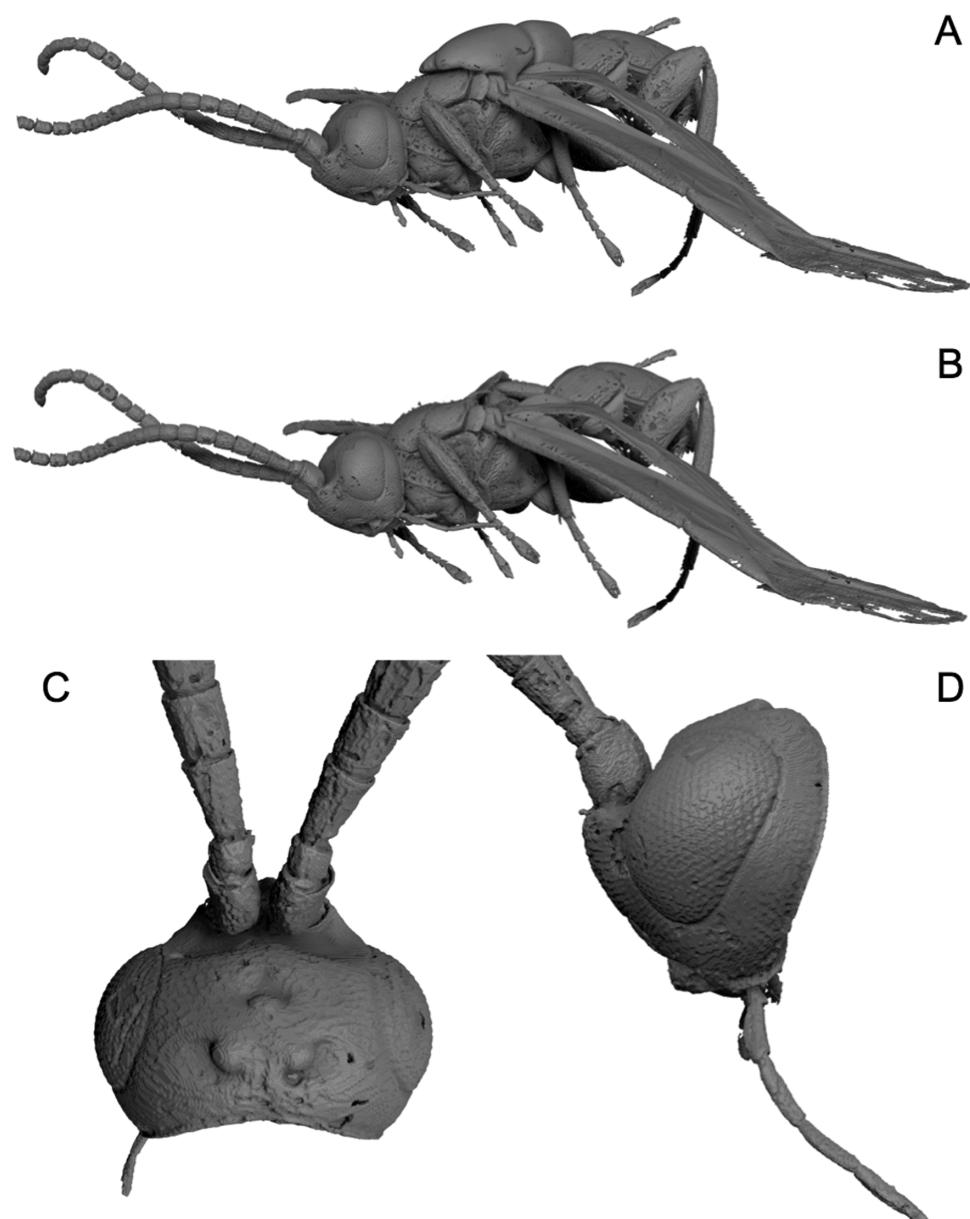

Length of body 3.25 mm and of fore wing c. 3.3 mm.

Antenna with 19 flagellomeres, median flagellomeres nearly quadrate, scapus weakly flared apically. Fore wing vein (RS+M)a strongly sinuate (Fig. 7). Width of head 1.6 x width of face. Face produced into a distinct point medio-dorsally between antennal sockets. Clypeus separated from face dorsally by a distinct groove. Hypoclypeal depression strongly convex medio-dorsally. Malar suture weak, curved. Occipital carina not weakened medio-dorsally. Frons strongly depressed laterally. Mesosoma 2 x longer than maximally high. Fore wing vein (RS+M)a strongly sinuate (Fig. 7). Fore wing vein 3RSa 1.5 x r-rs, 0.38 x 3RSb, vein (RS+M)a strongly sinuous. Hind wing

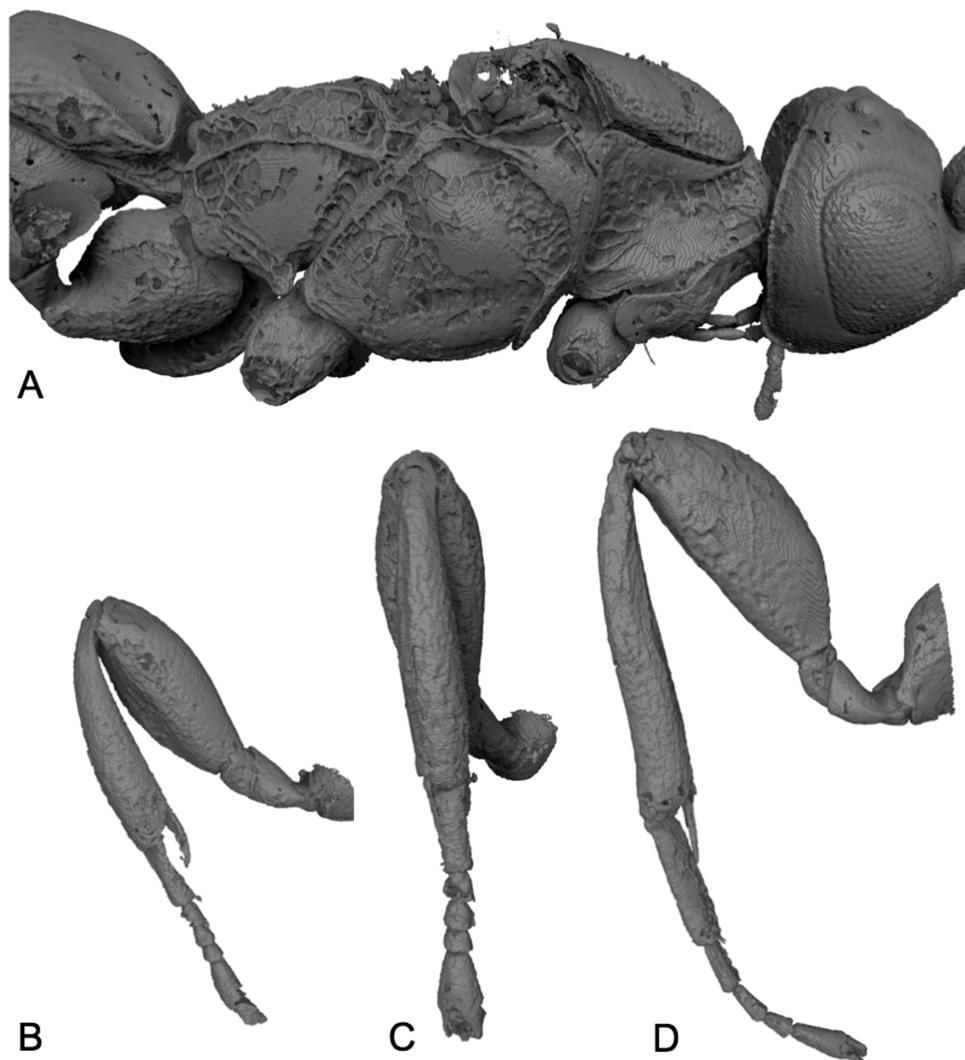

vein 1M 1.1 x M+CU, m-cu antefurcal. Fore tibia with weak longitudinal dorsal ridge (Fig. 5C). Fore telotarsus approximately 0.8 x length of fore basitarsus. First metasomal tergite approximately as long as posteriorly wide with submedial carinae apparently more prominent than medial carina. 2<sup>nd</sup> metasomal tergite longitudinally striate. 3<sup>rd</sup> tergite apparently entirely smooth.

**Notes.** Differs from extant species of *Mesocentrus* in having a distinct (though weak) midlongitudinal ridge on the fore tibia, a groove separating the clypeus from the face medio-dorsally, and flared basal flagellomeres. Whilst it could be argued that it might equally be placed in an extinct genus rather than *Mesocentrus*, the differences are rather slight and only the lack of dorsal separation of the clypeus in *Mesocentrus* would support its monophyly relative to the extinct species. Despite careful visual examination we were unable to determine whether the eyes of the fossil specimen are setose as in the extant species, and such detail is below the resolution of the synchrotron imaging system employed, though it seems likely that they are at least less setose if not completely glabrous.

**Etymology.** Name refers to its ancient European provenance.

**FIGURE 4.** *Mesocentrus palaeoeuropaea* sp. nov. 3D surface rendering based on synchrotron X-ray microtomography data. A, B, approximately lateral views, showing raw surface with air bubbled over posterior of mesosoma, and with air bubbles removed, respectively; C, D, head, dorsal and lateral aspects respectively.

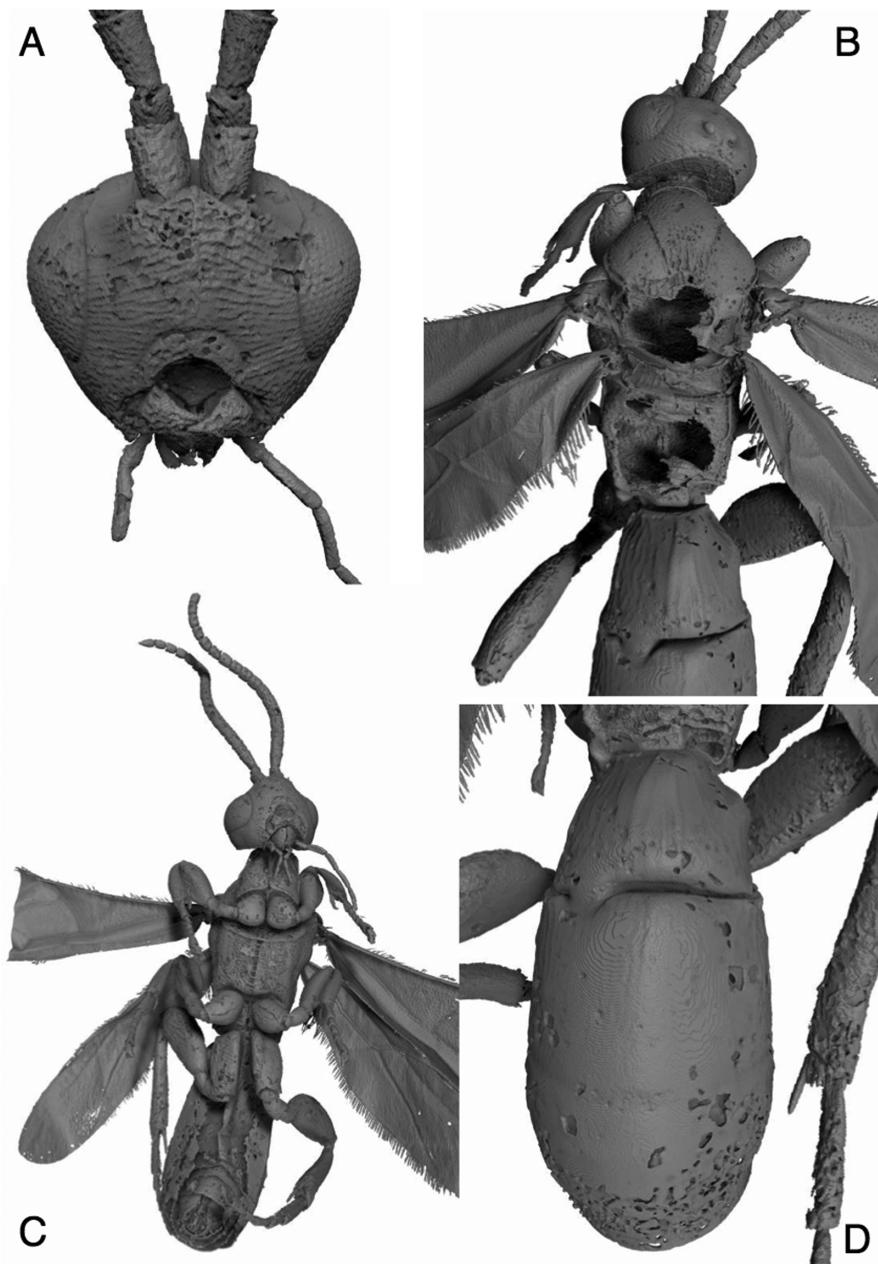

**FIGURE 5.** *Mesocentrus palaeoeuropaea* sp. nov. 3D surface rendering based on synchrotron X-ray microtomography data. A, mesosoma and most of 1<sup>st</sup> metasomal tergite, lateral view; B-D, fore, middle and hind legs respectively.

### Molecular results

The maximum likelihood tree generated by RAxML analysis with a log likelihood score of -24157.275645 was very similar to the bootstrap tree shown in Fig. 8 which includes bootstrap values of nodes with more than 50% support. *M. sasquatch* sp. nov. is recovered as expected with the other betylobraconines but without significant bootstrap support for any internal relationships, most likely because only it and one other betylobraconine have both 28S and CO1 sequence data. This clade was recovered among a mixture of Clinocentrini (*Rogadinae sensu stricto*) and one Tetratermini (*Lysiterminae*), and is well-separated from the remainder of the Rogadinae (viz. Aleiodini, Rogadini and Yeliconini). However, in agreement with Belokobylskij *et al.* (2008), the Facitorina which had previously been included within the Betylobraconinae are recovered with 100% bootstrap support within the tribe Yeliconini, as sister group to *Pseudoyelicones* + *Bulborogas*, which here are represented by additional sequences, again with high support.

Also of interest is the placement of the New Zealand genus *Rhinoprotoma*, which also has rather shortened fore tarsi and a protruding face though not pronounced as in the Betylobraconinae and Yeliconini or indeed, some

*Aleiodes*. Van Achterberg (1995) provisionally included it within the Rogadini, though here it was recovered belonging to the Aleiodini with 82% bootstrap support (Fig. 8), though that is only based on CO1 data. It does not appear to be a derived *Aleiodes*, however, despite the fact that several species of that genus similarly have very robust femora and shortened medial tarsal articles, viz. *A. globifemurus* Butcher & Quicke, *A. nonicones* Butcher & Quicke and *A. pseudicones* Butcher & Quicke (Butcher *et al.* 2012), thus providing an independent example of leg and facial modification in the subfamily.

**FIGURE 6.** *Mesocentrus palaeoeuropaea* sp. nov. A, 3D surface rendering based on synchrotron X-ray microtomography data. A, head, front view; B, mesosoma and 1<sup>st</sup> metasomal tergite; C, ventral view of head and body; D, dorsal view of remains of propodeum and metasoma.

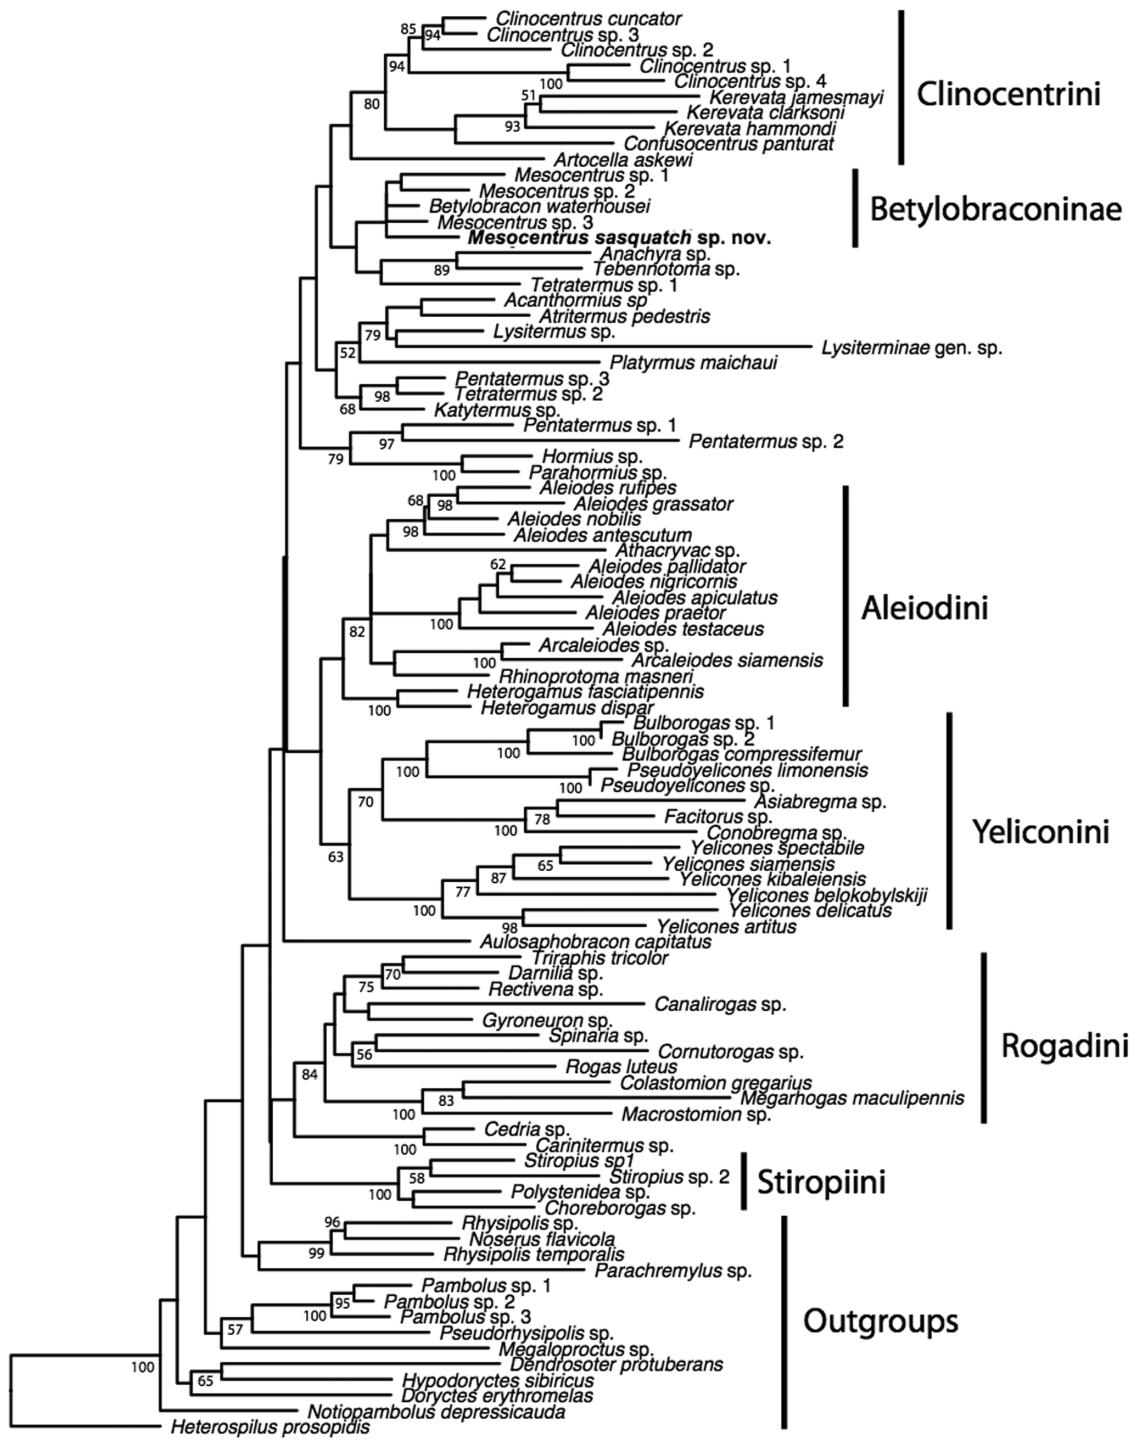

**FIGURE 7.** *Mesocentrus palaeoeuropaea* sp. nov. wings. 3D surface rendering based on synchrotron X-ray microtomography data showing wings.

## Discussion

The new species extend the known range of variation in the Betylobraconinae as well as placing a minimum age on the group, Baltic amber most probably having an age of at least 44 million years (Ritzkowski 1997). Preservation of the fossil specimen is generally very good, though the darkness of the amber limited visual inspection, whereas synchrotron x-ray has allowed visualisation of the specimen from all angles as well as enabling obscured parts to be digitally revealed. The specimen has two large bubbles directly on top of the posterior of the mesosoma (Fig. 4A), but while it was possible to remove these digitally (Fig. 4B), quite a lot of the underlying cuticle no longer exists (Fig. 6B). Nevertheless, the ability to remove them has permitted some remaining otherwise hidden detail to be discerned, e.g. the median carina on the metanotum, and the presence of at least a short mid-longitudinal carina on the propodeum anteriorly.

Although there is quite a strong difference in the development of the hypoclypeal depression in the two species, this feature is also quite variable in the genus *Mesocentrus*, as well as in the Opiinae. Notably the fossil species resembles the extant species in many features such as the near triangular conformation of the precoxal sulcus (Fig. 5A cf. 2A), some irregular to slightly longitudinal rugosity between notaui posteriorly, the extent and general quality of the body sculpture. In general, the extant species appears somewhat more derived in some features, especially in the degree of enlargement of the fore telotarsus and the reduction in the fore basitarsus, which consequently look far more like those of *Yelicones*. The slight ridge on the fore tibia like that in *M. palaeoeuropaea* sp. nov. is also present in many *Yelicones* species but and is likely involved in strengthening the segment in association with the robust nature of the fore leg rather than indicating membership of that group. *M. palaeoeuropaea* sp. nov., unlike any extant *Mesocentrus* species, has a distinct groove separating the clypeus medially from the face. In contrast, *M. sasquatch* sp. nov., with its larger number of flagellar segments than any other extant member of the genus, and more or less unmodified (not laterally depressed) frons, appears in these likely to have retained the plesiomorphic state.

**FIGURE 8.** Bootstrapped maximum likelihood molecular tree showing major in-group clades, and the position of *Mesocentrus sasquatch* sp. nov.

## Acknowledgements

We are greatly indebted to Claire Villemant (Paris) and Yves Braet (Brussels) for the loan of fascinating specimens from Papua New Guinea, Lars Vilhelmsen (Copenhagen) for arranging for DLJQ to study their collection of Baltic amber Ichneumonoidea. Kees van Achterberg kindly sent us a copy of his unpublished illustrations of *Promesocentrus* for comparison. The ANKA Synchrotron Radiation Facility is acknowledged for providing beam

time. Mark Shaw (National Museums of Scotland) and Darren Ward (Landcare Research, New Zealand) allowed us to use sequence data from some of their specimens. We would like to thank Chulalongkorn University Centenary Academic Development Project for support to DQ.
