Abstract

Rugosothynnus gen. nov. (type species *Rhagigaster corrugatus* Turner, 1910) is erected for 12 *Rhagigaster*-like species. Nine species are described and illustrated from Australia: *R. brunneus* sp. nov., *R. clypeatus* sp. nov., *R. confusus* sp. nov., *R. depresso* sp. nov., *R. fulvescens* sp. nov., *R. houstoni* sp. nov., *R. monteithae* sp. nov., *R. neocorrugatus* sp. nov. and *R. schichai* sp. nov. New combinations are proposed for *R. burnsi* (Given, 1959), comb. nov., *R. corrugatus* (Turner, 1910), comb. nov. and *R. tristis* (Smith, 1859), comb. nov. (all previously from genus *Rhagigaster* Guérin-Ménéville, 1838). A key to both sexes of all species is provided except for the females of *R. clypeatus* sp. nov., *R. depresso* sp. nov., *R. neocorrugatus* sp. nov. and *R. schichai* sp. nov. which are unknown.

Key words: Rhagigasterini, Thynninae, *Rugosothynnus*, wasps, new genus, new species, Australia

Introduction

The Thynninae is a large and predominantly Australian subfamily of Tiphidae (Hymenoptera). There are many undescribed taxa, and the subfamily has not been treated in toto for over a century, when the genera were revised by Turner (1910a) and the species by Turner (1907, 1908). A key to the genera of the tribe Rhagigasterini was given by Kimsey (1996) and the subfamily Thynninae by Kimsey (2004).

One of the larger genera included by Turner (1910a) was *Rhagigaster* Guérin-Ménéville, 1838. This genus, as well as *Dimorphothynnus* Turner, 1910, is distinguished by the shape of the metasoma in the male, which is long, narrow and parallel sided with the segments strongly constricted and the apical sternite (the hypopygium) with a strongly upturned apical spine. This genus is in need of revision, and has not been revised since Turner (1910a).

More recently Brown (2008) speculated on the division of *Rhagigaster* into several genera and also erected *Umbothynnus* Brown, 2008 for one species previously included in *Rhagigaster* as well as seven new species. He also revived the status of *Rhytidogaster* Turner, 1907, nom. praeocc., nec *Rhytidogaster* Agassiz, 1846, and proposed the replacement name *Rhytidothynnus* Brown, 2008

Subsequently the genus *Curvothynnus* Brown, 2010 was described by Brown (2010) for two species previously placed in *Rhagigaster*, and a third new genus, *Rugosothynnus* gen. nov., is described here for 12 similar-looking species. *Rhagigaster*, *Rhytidothynnus* and another new genus are currently being reviewed and will complete the revision of the *Rhagigaster* group of genera *sensu* Turner. Brown (2010) gave a key to the genera of the tribe Rhagigasterini and included *Rugosothynnus* gen. nov. as "genus R".

Materials and methods

The sexes are associated by coincident collecting including pairs collected *in copula*. Traditionally the male sex is selected for the holotype as these are better represented in collections. Where more than one specimen of a single female morphotype is collected with the same male, it is assumed the major association is the correct pairing of the sexes.

- 5(4). Frontal maculae large, occupying almost entire frons [SWA] *R. tristis* (Smith)
- Frontal maculae small [SWA] *R. houstoni* sp. nov.
- 6(1). Legs ferruginous, remainder of mesosoma black; pygidium weakly anterolaterally raised (Fig. 4) [SEQ, NNSW] *R. burnsi* (Given)
- Legs brown to black and concolorous with remainder of mesosoma; pygidium strongly anterolaterally raised (Figs 13, 31) . 7
- 7(6). T3–6 densely covered with fulvous setae especially medially (Fig. 45); T1–5 longitudinally rugosely punctate; body black [SWA] *R. fulvescens*, sp. nov.
- T3–6 sparsely covered with white setae; T1–5 deeply punctate; body brown [SWA] *R. brunneus* sp. nov.

Discussion

One of the biggest problems with *Rugosothynnus*-like genera in particular, and Thynninae in general, is that the sexes will miscouple so that there is no certainty that pairs found *in copula* are conspecific (Given 1954, 1959; Brown 1993, 2001b). The reason for this is unknown, although the dependence on the wingless female to be flown to a food source (whilst *in copula*) may be more important for the survival of a species than copulation resulting in egg fertilisation. Preliminary work on thynnine pheromones (Schiestl *et al.* 2003) suggest that females use a mixture of analogues (Griffiths *et al.* 2011) and this may possibly be a mechanism that allows for miscoupling (and speciation) to occur. This is untested, and currently the pheromones of *Rugosothynnus* and related genera have not been isolated or examined.

Within *Rugosothynnus* miscoupling of pairs were found in three instances: a male of *R. depressus* sp. nov. mounted with a female of *R. fulvescens* sp. nov. (from Tammin); a male of *R. depressus* sp. nov. mounted with a female of an unknown species of *Rugosothynnus* (from Perenjori); and a male of *R. houstoni* sp. nov. mounted with a female of *R. tristis* (from McDermid Rock).

Acknowledgments

I thank the curators of the above listed Institutions for the loan of specimens in their care. Most of this work was undertaken as part of my doctoral thesis under the guidance of Erik Shipp and Ian Naumann, and their help and guidance is gratefully appreciated. The research was undertaken while employed by the New South Wales Department of Agriculture at the then Biological and Chemical Research Institute and could not have been undertaken without the use of facilities, which is also appreciated. Erin Turek artfully re-inked the drawings for publication and Alan Andersen, Tropical Ecosystems Research Centre, CSIRO, Darwin provided invaluable assistance in allowing me access to photomicroscopy facilities. I also thank Arkady Lelej and the two anonymous referees for their considerable time input on the manuscript and their helpful comments.
