Abstract

A new species of torrent catfish, *Liobagrus hyeongsanensis*, is described from rivers and tributaries of the southeastern coast of Korea. The new species can be differentiated from its congeners by the following characteristics: a small size with a maximum standard length (SL) of 90 mm; body and fins entirely brownish-yellow without distinct markings; a relatively short pectoral spine (3.7–6.5 % SL); a reduced body-width at pectoral-fin base (15.5–17.9 % SL); 50–54 caudal-fin rays; 6–8 gill rakers; 2–3 (mostly 3) serrations on pectoral fin; 60–110 eggs per gravid female.

Key words: Amblycipitidae, *Liobagrus hyeongsanensis*, New species, Endemic, South Korea

Introduction

Species of the family Amblycipitidae, which comprises four genera, are found in swift freshwater streams in southern and eastern Asia, ranging from Pakistan across northern India to Malaysia, Korea, and Southern Japan (Chen & Lundberg 1995; Ng & Kottelat 2000; Kim & Park 2002; Wright & Ng 2008). Four species are endemic to the Korean peninsula: *Liobagrus andersoni* Regan, 1908, *L. mediadiposalis* Mori, 1936, *L. obesus* Son, Kim & Choo, 1987, and *L. somjinensis* Park & Kim, 2010. In a recent examination of populations of *L. mediadiposalis* in rivers and streams in Korea, we found evidence that populations restricted to rivers flowing to the eastern coast belonged to a distinct, unnamed species, which is described herein as *Liobagrus hyeongsanensis*.

Material and methods

Counts and measurements were taken following the procedures of Hubbs & Lagler (1964) and Wright & Ng (2008). Fin spines and soft rays were counted from radiographs, with the last two elements of the dorsal and anal fins being counted as one ray. Vertebral counts were also made from soft X-ray photographs (HA80, HITEX, Japan), with the three components associated with the Weberian apparatus being excluded (Chen & Lundberg 1995; Zhao *et al.* 2004). Measurements were taken using a digital caliper (to the nearest 0.1 mm). All specimens were deposited at the Faculty of Biology, Chonbuk National University, Jeonju, Korea (CNUC).

Liobagrus hyeongsanensis sp. nov. (Fig. 1)

Type material. Holotype: CNUC 38547, 84.1 mm standard length (SL); Hyeongsan River, Yangbuk-myeon, Gyeongju-si, South Korea, 35°49'58"N 129°24'41"E; J.Y. Park & S.H. Kim, 2 June 2013.

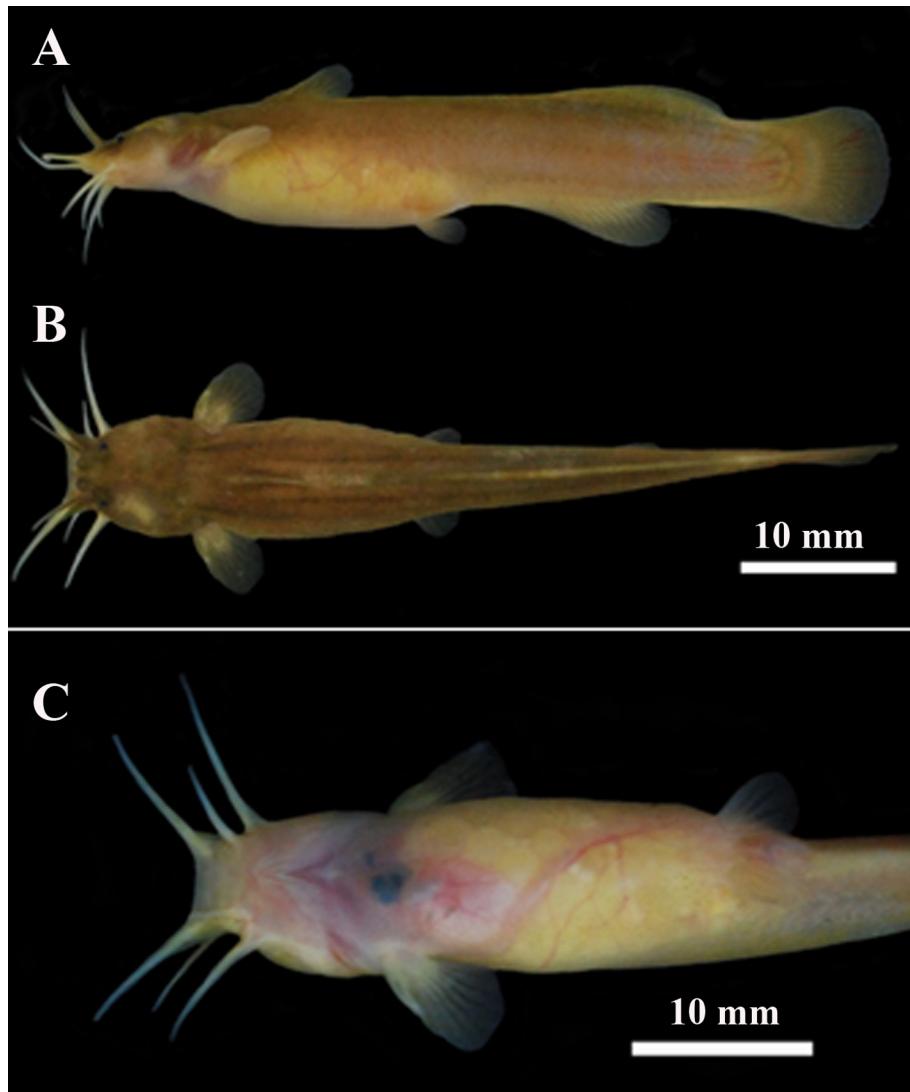

FIGURE 1. *Liobagrus hyeongsanensis*, sp. nov., CNUC 38547, holotype, 84.1 mm SL, Hyeongsan River, South Korea.

Paratypes: CNUC 38548–38567 (20), 57.1–84.1 mm SL; same data as holotype.

Nontypes: CNUC 38830–38854 (25), 41.8–67.8 mm SL; Bukcheon River, Hwangnyong-dong, Gyeongju-si, South Korea; J.Y. Park & S.H. Kim, 28 March 2010.

Diagnosis. *Liobagrus hyeongsanensis* is distinguished from all its congeners by a small size (a maximum of 90 mm SL, vs. 150–180 mm); a smaller number of eggs per gravid female (60–110 vs. 130–210); and a smaller number of serrations on the pectoral fin (2–3, mostly 3, vs. 3–6 or 0–3, smaller or vestigial); a slenderer body width at pectoral-fin base (15.5–17.9 % SL, vs. 17.1–21.9%); a relatively short pectoral spine (3.7–6.5 % SL, vs. 6.8–13.1%). The lower jaw is shorter than the upper jaw (vs. longer or equal), and the body and fins are entirely brownish yellow without any other markings (vs. a vertical broad yellowish crescent-shaped band on the caudal fin or black or whitish yellow outer margins of the dorsal and anal fins).

Description. Meristic and morphometric data are provided in Table 1. Asterisks indicate meristic values for holotype. Maximum size not exceeding 90 mm standard length. Body thin, compressed, and round; head depressed, caudal peduncle vertically depressed; dorsal and ventral profiles of body straight. Predorsal profile slightly sloping ventral from dorsal fin to occiput. Head depressed, broad. Eye small, dorsolateral, subcutaneous, ovoid. Snout rounded in dorsal view. Anterior nostril tubular, rim with fleshy flap forming short tube; posterior nostril porelike, rim posteriorly confluent with base of nasal barbel. Lateral line absent or vestigial.

Mouth terminal; lips thickened, papillate, premaxillary and mandibular toothpads curved, teeth small and ciliform or setiform, with upper jaw slightly longer than lower jaw. Four pairs of barbels: maxillary barbel longest, reaching base of pectoral spine; nasal barbel short, not reaching posterior margin of preoperculum; lateral

mandibular barbel long, reaching posterior margin of pectoral-fin base; medial mandibular barbel shortest of the four pairs of barbels, about half length of outer mental barbel, reaching to gill membrane.

TABLE 1. Morphometric and meristic data of *Liobagrus hyeongsanensis* (CNUC 38547–38567) and *L. mediadiposalis* (CNUC 37821–37838). H, holotype.

Inner-mental barbel length	7.2	20	6.5–10.6	8.9	1.2	18	7.4–9.1	8.3	0.5

Dorsal fin with II, 6 rays; origin closer to snout tip than to anal-fin origin, its posterior margin convex. Dorsal-fin spine a little shorter than pectoral-fin spine. Adipose fin base long, as long as or slightly exceeding anal-fin base length, confluent with caudal fin, its posterior margin convex. Pectoral fin with I, 7 rays, its origin anterior to vertical from posterior margin of operculum, partially covered by opercular membrane. Pectoral-fin spine sharp, short, with 2 (5), 3 (16) serrations on posterior edge. Pelvic fin with i, 5 rays; short, its origin located midway between dorsal and adipose fins, its tip not reaching base of anal fin. Anal fin with 15 (2), 16 (5), 17 (11), or 18 (3) rays, its distal margin rounded; anal fin short, origin slightly posterior to vertical through adipose-fin origin, posterior tip of anal fin not reaching beyond posterior margin of adipose fin. Caudal fin subtruncate, rounded. Vertebral column 38 (1), 39 (10), 40 (9), or 41 (1) post-Weberian elements. Gill rakers 6–8.

Coloration. See Figure 1 for general appearance. In life (Fig. 1): body generally brownish yellow, fading to light yellow on ventral surface, without distinct markings. All barbels pale gray. All fins with similar color to body, without any other markings.

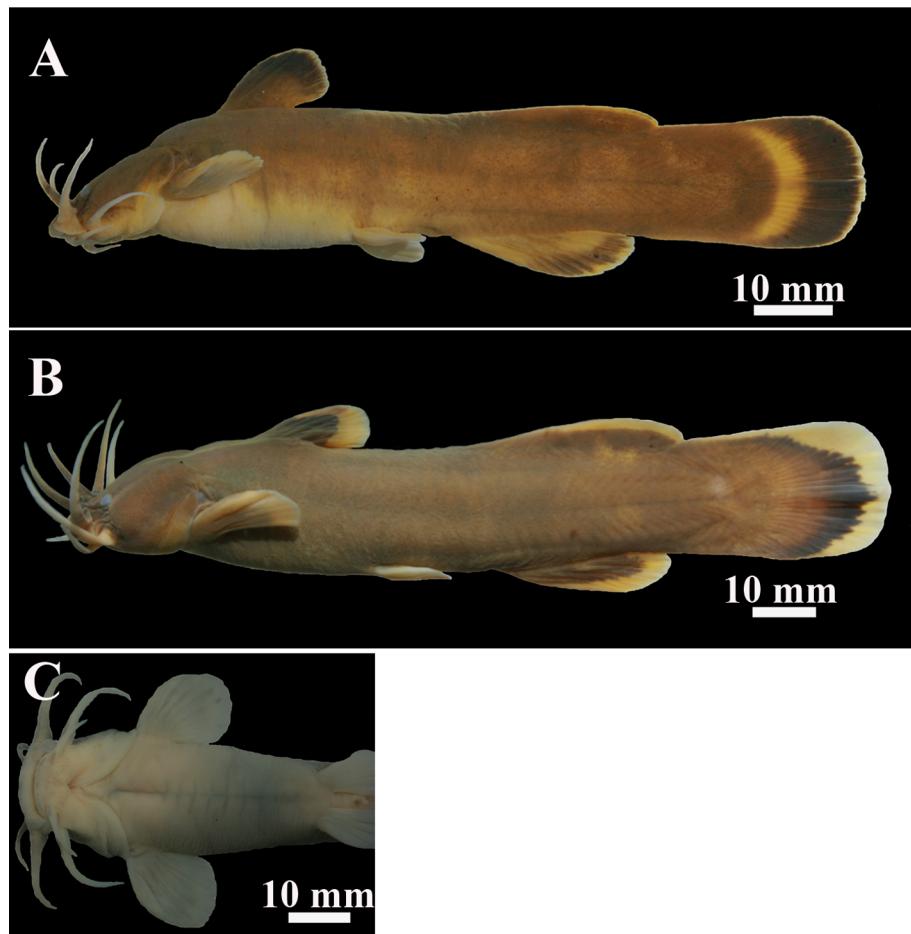

FIGURE 2. *Liobagrus somjinensis* (A), CNUC 39019, 87.7 mm SL, Somjin River, South Korea; *L. mediadiposalis* (B, C), CNUC 39020, 95.1 mm SL, Nakdong River, South Korea.

Distribution. *Liobagrus hyeongsanensis* is restricted to the rivers flowing to the eastern coast of Gyeongsangbuk-do, South Korea: Upper Hyeongsan and Taehwa Rivers (Fig. 4).

Sexual dimorphism. The adductor mandibulae in males is greatly expended during the spawning season, from late April to June.

Etymology. Named after the Hyeongsan River, the type locality. We propose the Korean name Donbang-Jaga-sari for this species.

Biology and habitat. *Liobagrus hyeongsanensis* is small, nocturnal and benthic. It inhabits the bottom stratum of running waters with moderately fast currents, in upper streams and valley streams. It is generally seen in shallow waters (0.3–0.8 m deep) with large or small stony or pebbly substrates. The spawning season is from late April to June. The adult females do not exceed 90.0 mm SL and lay a small number of eggs (60–110), 2.8–3.3 (3.1±0.2) mm in diameter.

Discussion

For more than a century, only three species of *Liobagrus* were known from the Korean Peninsula: *L. andersoni*, *L. mediadiposalis*, and *L. obesus* (Regan 1908c; Mori 1936; Son *et al.* 1987). Populations of *Liobagrus mediadiposalis* show marked variation in coloration as well as meristic and morphometric data. Close study of one such population, with a crescent-shaped band on the caudal fin and a pectoral-fin ray count of I, 6–7, resulted in its

recognition as a distinct species, *Liobagrus somjinensis* (Park & Kim 2010). While studying other populations of *Liobagrus mediadiposalis* in rivers and streams throughout Korea, we discovered an unnamed species clearly distinguishable from all its congeners.

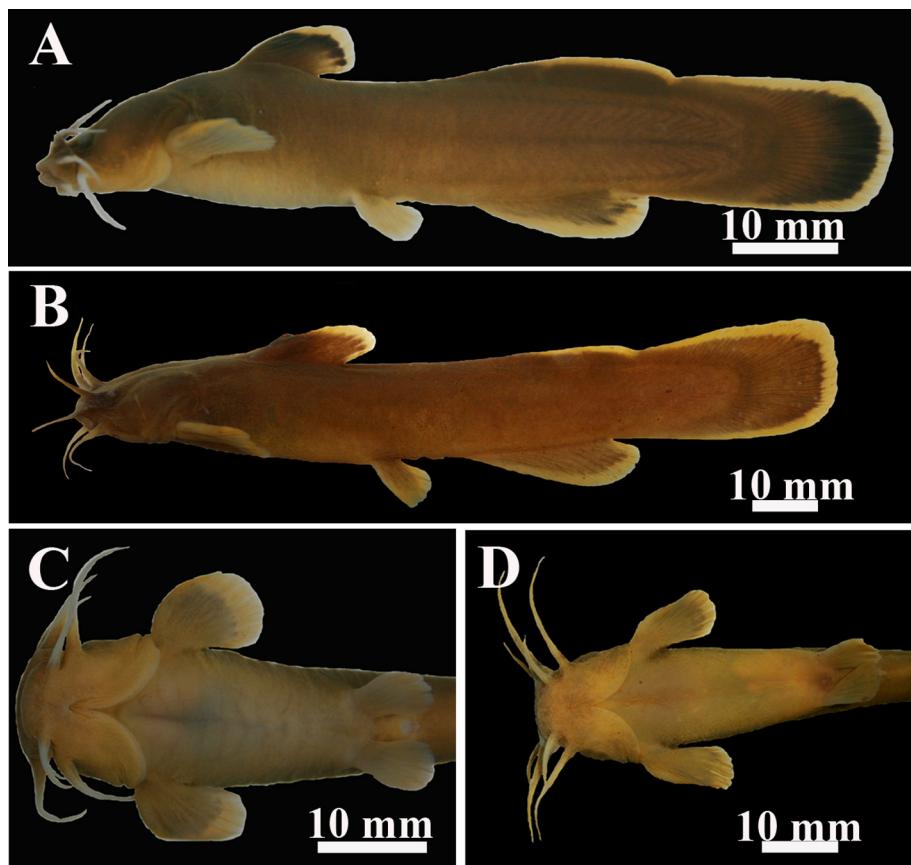

FIGURE 3. *Liobagrus andersoni* (A, C), CNUC 39021, 71.5 mm SL, Han River, South Korea; *L. obesus* (B, D), CNUC 39022, 95.5 mm SL, Mankyeong River, South Korea.

Compared with the original descriptions of *Liobagrus* (Hilgendorf 1878; Günther 1892; Regan 1904, 1908a, b, c; Oshima 1919; Nichols 1926; Wu 1930; Tchang 1935; Mori 1936; Son *et al.* 1987; Wright & Ng 2008; Park & Kim 2010) and based on coloration and meristic and morphometric data, we confirmed that *L. hyeongsanensis* is a species distinct from *L. mediadiposalis*. Of the Korean torrent catfishes, three species, *Liobagrus hyeongsanensis*, *L. somjinensis*, and *L. mediadiposalis* (Figs. 1–2), have the lower jaw shorter than the upper jaw, whereas *L. andersoni* and *L. obesus* have both jaws of equal length (Fig. 3). In particular, the number of serrations on the pectoral fin is 2–3 (mostly 3) in *L. hyeongsanensis* and 3–5 in *L. obesus*. Meanwhile, *Liobagrus andersoni* has 0–3 smaller or vestigial serrae. *Liobagrus hyeongsanensis* is a small-sized species with an overall brownish-yellow color over its entire body and fins (Fig. 1). In contrast, *Liobagrus somjinensis* has a broad vertical yellowish crescent-shaped band on the caudal fin, with a deep black outer margin, in addition to a deep black outer margin on the dorsal and anal fins (Fig. 2A). *Liobagrus mediadiposalis* has deep yellow outer margins on the black inner margins of all fins (Fig. 2B). *Liobagrus hyeongsanensis* is a small fish, reaching up to 90 mm SL (vs. 180 mm SL in *L. somjinensis* and *L. mediadiposalis*). *Liobagrus hyeongsanensis* has 2–3 (mostly 3) serrations on the pectoral fin (vs. 4–6 in *L. somjinensis* and *L. mediadiposalis*), 50–54 on the caudal-fin rays (vs. 57–61 in *L. somjinensis* and *L. mediadiposalis*), a relatively short pectoral spine (3.7–6.5 % SL, vs. 9.1–13.1% in *L. somjinensis* and 9.0–12.2% in *L. mediadiposalis*), and a thin body width at pectoral-fin base (15.5–17.9 % SL, vs. 17.3–19.6% in *L. somjinensis* and 17.1–20.0% in *L. mediadiposalis*). *Liobagrus hyeongsanensis* has a shorter lower than upper jaw, in contrast to its congeners (vs. lower jaw longer in *L. kingi*, *L. marginatus* and *L. marginatoides*; lower jaw of equal length in *L. andersoni*, *L. obesus*, *L. nigricauda*, *L. aequilabris* and *L. formosanus*). *Liobagrus hyeongsanensis* is further distinguished from *L. anguillicauda* and *L. nantensis* by having 4–6 serrations on the posterior edge of the pectoral-fin spine (vs. serrations absent) (Table 2).

TABLE 2. Comparison of *Liobagrus hyeongsanensis* and its two congeners based on present study.

	*Caudal-fin ray count	Gill raker count	Number of serrations on the pectoral fin	Number of eggs per gravid female	Maximum standard length (mm)	A vertical crescent band on the caudal fin
<i>L. mediadiposalis</i>	57–61	7–11	4–6	130–200	< 180	absent
<i>L. somjinensis</i>	57–61	7–9	4–6	134–230	< 180	present
<i>L. hyeongsanensis</i> sp.nov.	50–54	6–8	2–3	60–110	< 90	absent

*Includes principal caudal-fin rays, dorsal and ventral procurent caudal-fin rays.

Liobagrus hyeongsanensis is allopatrically distributed in smaller river systems including rivers and tributaries of the southeastern coast of Korea, compared to *L. somjinensis* and *L. mediadiposalis*. *Liobagrus somjinensis* inhabits rivers flowing to the western coast and some rivers flowing to the south coast, while *L. mediadiposalis* has an extended distribution, including some rivers inhabited by *L. somjinensis* (Fig. 4). *Liobagrus andersoni* is restricted to the Han River system, while *L. obesus* inhabits the western river systems of Keum, Yeongsan and Mangyeong River systems (Fig. 4). DNA analysis has also made it clear that the above three populations are separated well above the species level (Kim *et al.* 2006; Kim 2013).

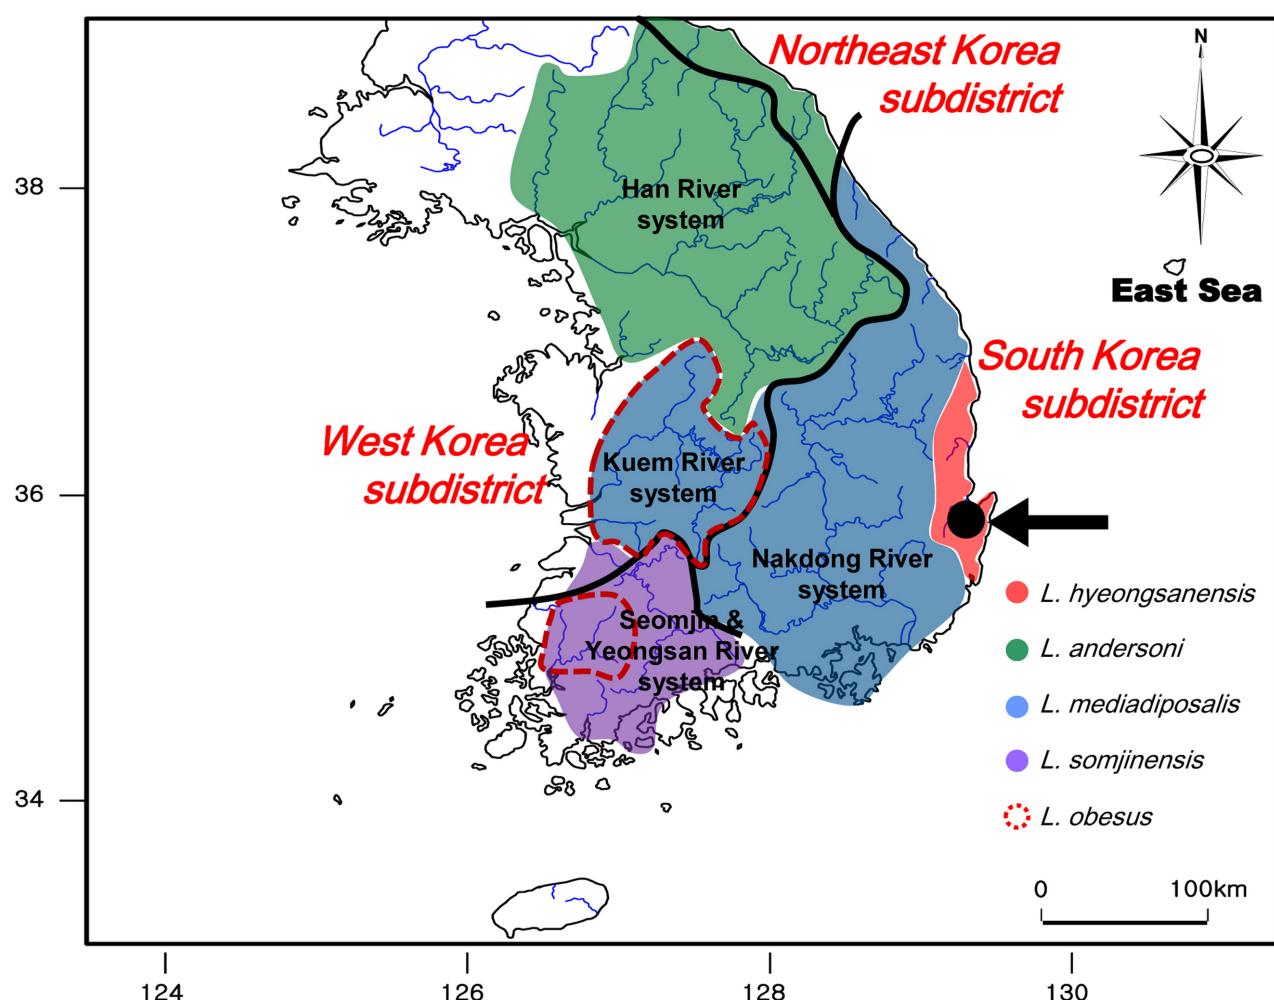

FIGURE 4. South Korea, showing distributions of *Liobagrus hyeongsanensis*, *L. somjinensis*, *L. mediadiposalis*, *L. obesus*, and *L. andersoni*. Dense black lines: Baekdudaegan mountain range, showing three biogeographical ranges of ichthyofaunal endemisms in the Korean Peninsula (modified from Kim 1997).

The Korean Peninsula has a long mountain region, the Baekdudaegan, consisting of at least 12 mountain ranges extending from North Korea to South Korea (Fig. 4). These hills were formed by active orogenic events

from the early Triassic to the Jurassic and from the late Oligocene to the early Miocene (Chough *et al.*, 2001; Sohn *et al.*, 2001). On this basis, the biogeographical distributions of freshwater fish fauna on the Korean Peninsula is characterized by three biogeographical regions (Northeast, West, and South Korea subdistricts) based on the endemic species of several large mountain ranges, which may serve on vicariant barriers or lead to allopatric distributions (Mori 1936; Kim 1997) (Fig. 4). In particular, the water systems (the upper Hyeongsan and Taehwa Rivers of the South Korea subdistrict) inhabited by *Liobagrus hyeongsanensis* are unique in that two other endemic fishes, *Squalidus multimaculatus* and *Iksookimia yongdokensis*, are restricted to these systems (Kim & Park 2002). This pattern of biogeographical isolation in the range encompassing basins of the Hyeongsan and Taehwa Rivers may be caused by the vicariant barrier of mountain ranges associated with a small isolated patch of middle Miocene marine sediment (Lee 1988). Some mountain ranges between the West and South subdistricts play an important role as a strong and long-term barrier to prevent recurrent gene flow and to split *Coreoleucisicus splendidus* populations into two genetically discrete subdistrict populations (Kim *et al.*, 2012). These mountain ranges appear to have effectively isolated species in different river systems, leading to a high level of endemism. The geographical pattern of speciation in *Liobagrus* has been reported previously also for other Korean freshwater fishes, including species in the families Cobitidae and Cyprinidae (Kim 1997; Kim & Park 2002; Kim *et al.* 2005; Park & Kim 2010).
